| ERR               | PDB Channel Sequence Error Flags<br><br>Only the lower M bits are implemented in this MCU.<br><br>0 Sequence error not detected on PDB channel's corresponding pre-trigger.<br>1 Sequence error detected on PDB channel's corresponding pre-trigger. ADCn block can be triggered for a conversion by one pre-trigger from PDB channel n. When one conversion, which is triggered by one of the pre-triggers from PDB channel n, is in progress, new trigger from PDB channel's corresponding pre-trigger m cannot be accepted by ADCn, and ERR[m] is set. Writing 0's to clear the sequence error flags. |

### 46.3.7 Channel n Delay 0 register (PDB\_CHnDLY0)

**Note:** This register is internally buffered, and any values written to the register are written to its internal buffer instead; in other words, the internal device bus does not write directly to this register. The value in this register's internal buffer is loaded into this register only after "1" is written to the SC[LDOK] bit.

Address: 0h base + 18h offset + (40d × i), where i=0d to 3d

## 46.4 Functional description

### 46.4.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared to several different digital values. If the PDB is enabled, then a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on a selected trigger input source, or if a software trigger is selected and the Software Trigger bit (SC[SWTRIG]) is written with 1. For each channel, a delay  $m$  determines the time between assertion of the trigger input event to the time at which changes in the pre-trigger  $m$  output signal are started. The time is defined as:

- Trigger input event to pre-trigger  $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$  peripheral clock cycles
- Add 1 additional peripheral clock cycle to determine the time when the channel trigger output changes.

Each channel is associated with 1 ADC block. PDB channel  $n$  pre-trigger outputs 0 to  $M$ ; each pre-trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block before the actual trigger occurs. When the ADC receives the rising edge of the trigger, the ADC will start the conversion according to the precondition determined by the pre-triggers. The ADC contains  $M$  sets of configuration and result registers, allowing it to alternate conversions between  $M$  different analog sources (like a ping-pong game). The pre-trigger outputs are used to specify which signal will be sampled next. When a pre-trigger  $m$  is asserted, the ADC conversion is triggered with set  $m$  of the configuration and result registers.

The waveforms shown in the following diagram show the pre-trigger and trigger outputs of PDB channel  $n$ . The delays can be independently set using the channel delay registers (CH $n$ DL $Ym$ ), and the pre-triggers can be enabled or disabled using the PDB Channel Pre-Trigger Enables (CH $n$ C1[EN[ $m$ ]]).

Figure 46-8. Pre-trigger and trigger outputs

The delay in the channel delay register ( $CHnDLYm$ ) can be optionally bypassed, if the PDB Channel Pre-Trigger Output Select ( $CHnC1[TOS[m]]$ ) is cleared. In this case, when the trigger input event occurs, the pre-trigger  $m$  is asserted after 2 peripheral clock cycles.

The PDB can be configured for back-to-back operation. Back-to-back operation enables the ADC conversion completions to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back operation is enabled by setting the PDB Channel Pre-Trigger Back-to-Back Operation Enable ( $CHnC1[BB[m]]$ ), then the delay  $m$  is ignored and the pre-trigger  $m$  is asserted 2 peripheral cycles after the acknowledgment  $m$  is received. The acknowledgment connections in this MCU are described in [Back-to-back acknowledgment connections](#).

When a pre-trigger from a PDB channel  $n$  is asserted, the associated lock of the pre-trigger becomes active. The associated lock is released by the rising edge of the corresponding  $ADCnSC1[COCO]$ ; the  $ADCnSC1[COCO]$  should be cleared after the conversion result is read, so that the next rising edge of  $ADCnSC1[COCO]$  can be generated to clear the lock later. The lock becomes inactive when:

- the rising edge of corresponding  $ADCnSC1[COCO]$  occurs,
- or the corresponding PDB pre-trigger is disabled,
- or the PDB is disabled

The channel  $n$  trigger output is suppressed when any of the locks of the pre-triggers in channel  $n$  is active.

- If a new pre-trigger  $m$  asserts when there is active lock in the PDB channel  $n$ , then a PDB Channel Sequence Error Flag ( $CHnS[ERR[m]]$ , associated with the pre-trigger  $m$ ) is set. If the PDB Sequence Error Interrupt Enable ( $SC[PDBEIE]$ ) is set, then the sequence error interrupt is generated. A sequence error typically happens because the delay  $m$  is set too short and the pre-trigger  $m$  asserts before the previously triggered ADC conversion finishes.
- If the pre-trigger delay is 0 cycles, then both channels will flag a PDB channel sequence error and ADC will not perform a conversion.

The PDB reports PDB channel sequence errors only for pre-triggers in same PDB channel. For situations when PDB triggering is done through different PDB channels, software must ensure sufficient delays in between the pre-triggers.

When the PDB counter reaches the value ( $CNT + 1$ ), the PDB Interrupt Flag ( $SC[PDBIF]$ ) is set. A PDB interrupt can be generated if the PDB Sequence Error Interrupt Enable ( $SC[PDBEIE]$ ) is set and the DMA Enable ( $SC[DMAEN]$ ) is cleared. If the DMA Enable ( $SC[DMAEN]$ ) is set, then the PDB requests a DMA transfer when the PDB Interrupt Flag ( $SC[PDBIF]$ ) is set.

The modulus value in the Modulus register (MOD) is used to reset the counter back to zero at the end of the count. If the Continuous Mode Enable (SC[CONT]) is set, then the counter will then resume a new count; otherwise, the counter operation will stop until the next trigger input event occurs.

### 46.4.2 PDB trigger input source selection

The PDB has up to 3 trigger input sources: software trigger, internal trigger, external trigger (via a pin). They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through SC[SWTRIG].

For the trigger input sources implemented in this MCU, see chip configuration information.

### 46.4.3 Pulse-Out's

PDB can generate pulse outputs of configurable width.

- When the PDB counter reaches the value set in POyDLY[DLY1], then the Pulse-Out goes high.
- When the PDB counter reaches POyDLY[DLY2], then it goes low.

POyDLY[DLY2] can be set either greater or less than POyDLY[DLY1].

ADC pre-trigger/trigger outputs and Pulse-Out generation have the same time base, because they both share the PDB counter. The pulse-out connections implemented in this MCU are described in the device's chip configuration details.

### Pulse-Out generation with $DLY2 > DLY1$

### Pulse-Out generation with $DLY1 > DLY2$

**Figure 46-9. How Pulse Out is generated**

## 46.4.4 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)
- PDB Interrupt Delay register (IDLY)

- PDB Channel  $n$  Delay  $m$  register (CH $n$ DLY $m$ )
- PDB Pulse-Out  $y$  Delay register (PO $y$ DLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized in the next table.

**Table 46-9. When delay registers are updated**

| SC[LDMOD] | Update to the delay registers                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| 00        | The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].            |
| 01        | The PDB counter reaches PDB_MOD[MOD] + 1 value, after 1 is written to SC[LDOK].                                             |
| 10        | A trigger input event is detected after 1 is written to SC[LDOK].                                                           |
| 11        | Either the PDB counter reaches PDB_MOD[MOD] + 1 value or a trigger input event is detected, after 1 is written to SC[LDOK]. |

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

**Figure 46-10. Registers update with SC[LDMOD] = 00**

Figure 46-11. Registers update with SC[LDMOD] = x1

## 46.4.5 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 46-10. PDB interrupt summary

| Interrupt                    | Flags      | Enable bit                      |
|------------------------------|------------|---------------------------------|
| PDB Interrupt                | SC[PDBIF]  | SC[PDBIE] = 1 and SC[DMAEN] = 0 |
| PDB Sequence Error Interrupt | CHnS[ERRm] | SC[PDBEIE] = 1                  |

## 46.4.6 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

## 46.5 Application information

### 46.5.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

# Chapter 47

## FlexTimer Module (FTM)

### 47.1 Chip-specific FTM information

#### 47.1.1 Instantiation Information

The following table lists the FTM instances each chip in the product series and summarizes features that vary across the products and instances.

**Table 47-1. FTM instances and features**

| Chips    | Instances | Channels | Fault inputs | FTM modulation | Quadrature Decoder | Hall sensor support | Dithering |
|----------|-----------|----------|--------------|----------------|--------------------|---------------------|-----------|
| S32K116  | FTM0      | 8        | 1            | Yes            | No                 | No                  | No        |
|          | FTM1      | 8        | 3            | No             | Yes                | No                  | Yes       |
| S32K118  | FTM0      | 8        | 4            | Yes            | No                 | No                  | No        |

*Table continues on the next page...*

**Table 47-1. FTM instances and features (continued)**

| Chips   | Instances | Channels | Fault inputs | FTM modulation | Quadrature Decoder | Hall sensor support | Dithering |
|---------|-----------|----------|--------------|----------------|--------------------|---------------------|-----------|
| S32K148 | FTM4      | 8        | 2            | No             | No                 | No                  | No        |
|         | FTM5      | 8        | 2            | No             | No                 | No                  | No        |
|         | FTM0      | 8        | 4            | Yes            | No                 | No                  | No        |
|         | FTM1      | 8        | 4            | No             | Yes                | Yes                 | Yes       |
|         | FTM2      | 8        | 4            | No             | Yes                | Yes                 | Yes       |
|         | FTM3      | 8        | 4            | Yes            | No                 | No                  | No        |
|         | FTM4      | 8        | 2            | No             | No                 | No                  | No        |
|         | FTM5      | 8        | 2            | No             | No                 | No                  | No        |
|         | FTM6      | 8        | 2            | No             | No                 | No                  | No        |
|         | FTM7      | 8        | 2            | No             | No                 | No                  | No        |

**NOTE**

Not all the registers shown in memory map of FTM are implemented in each variant/instance of S32K14x. See the above table for available features and hence the register implementation.

For all products in the series, all FTM instances have these features:

- Global time base
- Filters on input channel
- Filter on fault channel
- Half cycle reload
- Separate deadtime on channel pairs

FTM global load enable is implemented through SIM\_FTMOPT1[FTMGLDOK]. Refer to [Global Load](#) and SIM\_FTMOPT1[FTMGLDOK].

Wait mode is not supported on this device. See [Module operation in available power modes](#) for details on available power modes.

## 47.1.2 FTM Interrupts

The FlexTimer has multiple sources of interrupt. Refer to the DMA\_Interrupt\_mapping.xlsm attached with this Reference Manual. When an FTM interrupt occurs, read the FTM status registers (FMS, SC, and STATUS) to determine the exact interrupt source.

### 47.1.3 FTM Fault Detection Inputs

The following fault detection input options for the FTM modules are selected via the SIM\_FTMOPT0 register. The external pin option is selected by default.

- FTM0 FAULT0 = FTM0\_FLT0 pin or TRGMUX output
- FTM0 FAULT1 = FTM0\_FLT1 pin or TRGMUX output
- FTM0 FAULT2 = FTM0\_FLT2 pin or TRGMUX output
- FTM0 FAULT3 = FTM0\_FLT3 pin
  
- FTM1 FAULT0 = FTM1\_FLT0 pin or TRGMUX output
- FTM1 FAULT1 = FTM1\_FLT1 pin or TRGMUX output
- FTM1 FAULT2 = FTM1\_FLT2 pin or TRGMUX output
- FTM1 FAULT3 = FTM1\_FLT3 pin
  
- FTM2 FAULT0 = FTM2\_FLT0 pin or TRGMUX output
- FTM2 FAULT1 = FTM2\_FLT1 pin or TRGMUX output
- FTM2 FAULT2 = FTM2\_FLT2 pin or TRGMUX output
- FTM2 FAULT3 = FTM2\_FLT3 pin
  
- FTM3 FAULT0 = FTM3\_FLT0 pin or TRGMUX output
- FTM3 FAULT1 = FTM3\_FLT1 pin or TRGMUX output
- FTM3 FAULT2 = FTM3\_FLT2 pin or TRGMUX output
- FTM3 FAULT3 = FTM3\_FLT3 pin
- FTM4 FAULT0 = FTM4\_FLT0 pin
  
- FTM4 FAULT1 = FTM4\_FLT1 pin
  
- FTM5 FAULT0 = FTM5\_FLT0 pin
  
- FTM5 FAULT1 = FTM5\_FLT1 pin
  
- FTM6 FAULT0 = FTM6\_FLT0 pin
  
- FTM6 FAULT1 = FTM6\_FLT1 pin
  
- FTM7 FAULT0 = FTM7\_FLT0 pin
  
- FTM7 FAULT1 = FTM7\_FLT1 pin

Figure 47-1. Fault detection inputs

#### 47.1.4 FTM Hardware Triggers and Synchronization

The FlexTimer support external hardware trigger input which can be used for timer dynamic synchronization between multiple FlexTimers or counter reset. The FlexTimer hardware trigger are implemented as following.

FTM0:

- FTM0 hardware trigger 0 = TRGMUX trigger output
- FTM0 hardware trigger 1 = SIM\_FTMOPT1[FTM0SYNCBIT]
- FTM0 hardware trigger 2 = FTM0\_FLT0 pin

FTM1:

- FTM1 hardware trigger 0 = TRGMUX trigger output
- FTM1 hardware trigger 1 = SIM\_FTMOPT1[FTM1SYNCBIT]
- FTM1 hardware trigger 2 = FTM1\_FLT0 pin

FTM2:

- FTM2 hardware trigger 0 = TRGMUX trigger output
- FTM2 hardware trigger 1 = SIM\_FTMOPT1[FTM2SYNCBIT]
- FTM2 hardware trigger 2 = FTM2\_FLT0 pin

FTM3:

- FTM3 hardware trigger 0 = TRGMUX trigger output
- FTM3 hardware trigger 1 = SIM\_FTMOPT1[FTM3SYNCBIT]
- FTM3 hardware trigger 2 = FTM3\_FLT0 pin

FTM4

- FTM4 hardware trigger 0 = TRGMUX trigger output
- FTM4 hardware trigger 1 = SIM\_FTMOPT1[FTM4SYNCBIT]
- FTM4 hardware trigger 2 = FTM4\_FLT0 pin

#### FTM5

- FTM5 hardware trigger 0 = TRGMUX trigger output
- FTM5 hardware trigger 1 = SIM\_FTMOPT1[FTM5SYNCBIT]
- FTM5 hardware trigger 2 = FTM5\_FLT0 pin

#### FTM6

- FTM6 hardware trigger 0 = TRGMUX trigger output
- FTM6 hardware trigger 1 = SIM\_FTMOPT1[FTM6SYNCBIT]
- FTM6 hardware trigger 2 = FTM6\_FLT0 pin

#### FTM7

- FTM7 hardware trigger 0 = TRGMUX trigger output
- FTM7 hardware trigger 1 = SIM\_FTMOPT1[FTM7SYNCBIT]
- FTM7 hardware trigger 2 = FTM7\_FLT0 pin

The hardware trigger source can be from many other modules via TRGMUX, like LPIT, Low Power Timer, CMP, etc. It also supports FlexTimer's self trigger outputs, ex: counter initialization trigger (init\_trig) and channel match trigger (ext\_trig), through the flexible TRGMUX module.

**Figure 47-2. Hardware triggers**

The FlexTimer trigger outputs are also usually used as trigger source by other modules, for example, the above diagram shows a case of triggering PDB and ADC. See [Instantiation Information](#) and TRGMUX connectivity [Module interconnectivity](#) for details.

### 47.1.5 FTM Input Capture Options

The following channel 0 input capture source options are selected via SIM\_FTMOPT1. The external pin option is selected by default.

- FTM1 channel 0 input capture = FTM1\_CH0 pin or CMP0 output
- FTM2 channel 0 input capture = FTM2\_CH0 pin or CMP0 output
- FTM2 channel 1 input capture = FTM2\_CH1 pin or exclusive OR of FTM2\_CH0, FTM2\_CH1, and FTM1\_CH1. See [FTM Hall sensor support](#).

### 47.1.6 FTM Hall sensor support

For 3 phase motor control sensor-ed applications the use of Hall sensors, generally 3 sensors placed 120 degrees apart around the rotor, are deployed to detect position and speed. Each of the 3 sensors provides a pulse that applied to an input capture pin, can then be analyzed and both speed and position can be deduced. To simplify the calculations required by the CPU on each hall sensor's input, if all 3 inputs are "exclusively OR'd" into one timer channel and the free running counter is refreshed on every edge then this can simplify the speed calculation.

Via the SIM module and SIM\_FTMOPT1 register the FTM2CH1SEL bit provides the choice of normal FTM2\_CH1 input or the XOR of FTM2\_CH0, FTM2\_CH1 and FTM1\_CH1 pins that will be applied to FTM2\_CH1.

#### NOTE

If the user utilizes FTM1\_CH1 to be an input to FTM2\_CH1, FTM1\_CH0 can still be utilized for other functions.

Figure 47-3. FTM Hall Sensor Configuration

### 47.1.7 FTM Modulation Implementation

FTM0 and FTM3 support a modulation function where the output channels when configured as PWM or Output Compare mode modulate another timer output when the channel signal is asserted. Any of the 8 channels of FTM0 and any of the 8 channels of FTM3 can be configured to support this modulation function.

The SIM\_FTMOPT1 register has control bits (FTMxCHySEL) that allow the user to select normal PWM/Output Compare mode on the corresponding FTM timer channel or modulate with FTM1\_CH1. The diagram below shows the implementation for FTM0. FTM3 has similar implementation controlled by SIM\_FTMOPT1[FTM3CHySEL] on each of its 8 channels with modulation possible via FTM2\_CH1. See [SIM](#) chapter for further information.

When FTM1\_CH1 is used to modulate an FTM0 channel, then the user must configure FTM1\_CH1 to provide a signal that has a higher frequency than the modulated FTM0 channel output. Also it limits the use of the FTM1\_CH0 function, as the FTM1\_CH1 will be programmed to provide a 50% duty PWM signal and limit the start and modulus values for the free running counter. FTM2 has a similar restriction when FTM2\_CH1 is used for modulating an FTM3 channel.

Figure 47-4. FTM Output Modulation

### 47.1.8 FTM Global Time Base

This chip provides the optional FTM global time base feature, see [Global time base \(GTB\)](#).

FTM supports global timer base through the GTB feature. Any of the FTM module could be used as the GTB\_EN source. The global timer base only allows the FTM counters to start their operation synchronously, it does not automatically provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during misc FTM operation.

**Figure 47-5. FTM global time base system interconnection**

### 47.1.9 FTM BDM and debug halt mode

In the FTM chapter, references to the chip being in "BDM" are the same as the chip being in "debug halt mode".

#### 47.1.9.1 FTM output channel state retention

This device supports optional state retention of FTM channel in case of no clock condition (CLKS=2'b00). See SIM\_MISCTRL0[FTMx\_OBE\_CTRL] for enabling this feature.

### 47.1.10 FTM fixed frequency clock

This device requires that the input fixed frequency clock (mapped to RTC\_CLK (shown in [Table 27-9](#)), should be restricted to 1/4th of the FTM System clock.

### 47.1.11 S32K11X to S32K14X difference

See [Differences between S32K14x/S32K14xW, and S32K11x](#), for differences arising out of CPU and interrupt latency impacting timed events when comparing S32K14X and S32K11X variants.

## 47.1.11.1 Filter differences in S32K14x, S32K14xW, and S32K11x devices

The following table shows the filter differences between S32K14x, S32K14xW, and S32K11x devices.

| S32K14x                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | S32K11x and S32K14xW                                                                                                                                                                                                                                                                                |                                                                                                                                                         |                                                                                       |                                                                                                                                                        |                |                                                                                   |                |                                                                                                                                   |                                                                                                                                              |                |                                                                                                        |                |                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                          |                 |                                                                                       |                                                                                                                                                        |                |                                                                                   |                |                                                                                                                                   |                                                                                                                                              |                |                                                                                                        |                |                                                                                                                                                         |

## NOTE

The corresponding sections refer to S32K11x implementation.  
For S32K14x, see the differences listed in the table above.

## 47.2 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

### 47.2.1 Features

The FTM features include:

- FTM source clock is selectable
  - Source clock can be the FTM input clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the FTM input clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter

- It can be a free-running counter or a counter with initial and final value
- The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels. One unique prescaler is available for all filters
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- The generation of an interrupt when a register reload point occurs
- Synchronized loading of write buffered FTM registers
- Half cycle and Full cycle register reload capacity
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input capture mode

- Direct access to input pin states
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event
- The FTM channels can be selected to generate a trigger pulse on channel output instead of a PWM
- Dithering capability to simulate fine edge control for both PWM period or PWM duty cycle

### 47.2.2 Modes of operation

When the chip is in an active Debug mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

### 47.2.3 Block Diagram

The FTM uses one input/output (I/O) pin per channel, CH<sub>n</sub> (FTM channel (n)) where n is the channel number (0–7).

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

Figure 47-6. FTM Block Diagram

## 47.3 FTM signal descriptions

Table 47-2 shows the user-accessible signals for the FTM.

**Table 47-2. FTM signal descriptions**

| Signal | Description                                                                             | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXTCLK | External clock. FTM external clock can be selected to drive the FTM counter.            | I   | The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of FTM input clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.                                                                                                                                                                                                                                                                                                                                              |
| CHn    | FTM channel (n), where n can be 7-0                                                     | I/O | Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| FAULTj | Fault input (j), where j can be 3-0                                                     | I   | The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINE register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTJEN bit in the FLTCTRL register. |
| PHA    | Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A. | I   | The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder Mode</a> .                                                                                                                                                                                                                                                                                                                                                                                           |
| PHB    | Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B. | I   | The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder Mode</a> .                                                                                                                                                                                                                                                                                                                                                                                           |

## 47.4 Memory map and register definition

### 47.4.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

**NOTE**

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance.

**47.4.2 Register descriptions**

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved. Double buffered register writes must be done using 32-bit operations.

**47.4.3 FTM register descriptions****47.4.3.1 FTM memory map**

FTM0 base address: 4003\_8000h

FTM1 base address: 4003\_9000h

FTM2 base address: 4003\_A000h

FTM3 base address: 4002\_6000h

FTM4 base address: 4006\_E000h

FTM5 base address: 4006\_F000h

FTM6 base address: 4007\_0000h

FTM7 base address: 4007\_1000h

| Offset | Register                              | Width<br>(In bits) | Access | Reset value |
|--------|---------------------------------------|--------------------|--------|-------------|
| 0h     | Status And Control (SC)               | 32                 | RW     | 0000_0000h  |
| 4h     | Counter (CNT)                         | 32                 | RW     | 0000_0000h  |
| 8h     | Modulo (MOD)                          | 32                 | RW     | 0000_0000h  |
| Ch     | Channel (n) Status And Control (C0SC) | 32                 | RW     | 0000_0000h  |
| 10h    | Channel (n) Value (C0V)               | 32                 | RW     | 0000_0000h  |
| 14h    | Channel (n) Status And Control (C1SC) | 32                 | RW     | 0000_0000h  |

*Table continues on the next page...*

| Offset      | Register                                                    | Width<br>(In bits) | Access | Reset value |
|-------------|-------------------------------------------------------------|--------------------|--------|-------------|
| 18h         | Channel (n) Value (C1V)                                     | 32                 | RW     | 0000_0000h  |
| 1Ch         | Channel (n) Status And Control (C2SC)                       | 32                 | RW     | 0000_0000h  |
| 20h         | Channel (n) Value (C2V)                                     | 32                 | RW     | 0000_0000h  |
| 24h         | Channel (n) Status And Control (C3SC)                       | 32                 | RW     | 0000_0000h  |
| 28h         | Channel (n) Value (C3V)                                     | 32                 | RW     | 0000_0000h  |
| 2Ch         | Channel (n) Status And Control (C4SC)                       | 32                 | RW     | 0000_0000h  |
| 30h         | Channel (n) Value (C4V)                                     | 32                 | RW     | 0000_0000h  |
| 34h         | Channel (n) Status And Control (C5SC)                       | 32                 | RW     | 0000_0000h  |
| 38h         | Channel (n) Value (C5V)                                     | 32                 | RW     | 0000_0000h  |
| 3Ch         | Channel (n) Status And Control (C6SC)                       | 32                 | RW     | 0000_0000h  |
| 40h         | Channel (n) Value (C6V)                                     | 32                 | RW     | 0000_0000h  |
| 44h         | Channel (n) Status And Control (C7SC)                       | 32                 | RW     | 0000_0000h  |

## 47.4.3.2 Status And Control (SC)

### 47.4.3.2.1 Offset

| Register | Offset |
|----------|--------|
| SC       | 0h     |

### 47.4.3.2.2 Function

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, filter prescaler, and prescaler factor.

This register also contains the output enable control bits and the reload opportunity flag control.

These controls relate to all channels within this module.

### 47.4.3.3 Counter (CNT)

#### 47.4.3.3.1 Offset

| Register | Offset |
|----------|--------|
| CNT      | 4h     |

#### 47.4.3.3.2 Function

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

### 47.4.3.3.3 Diagram

### 47.4.3.3.4 Fields

| Field         | Function      |
|---------------|---------------|
| 31-16<br>—    | Reserved      |
| 15-0<br>COUNT | Counter Value |

## 47.4.3.4 Modulo (MOD)

### 47.4.3.4.1 Offset

| Register | Offset |
|----------|--------|
| MOD      | 8h     |

### 47.4.3.4.2 Function

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock cycle, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writes to the MOD register are done on its write buffer. The MOD register is updated with its write buffer value according to [Registers updated from write buffers](#). If FTMEN = 0, a write to SC register resets manually this write coherency mechanism.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

#### 47.4.3.4.3 Diagram

#### 47.4.3.4.4 Fields

| Field       | Function            |
|-------------|---------------------|
| 31-16<br>—  | Reserved            |
| 15-0<br>MOD | MOD<br>Modulo Value |

### 47.4.3.5 Channel (n) Status And Control (C0SC - C7SC)

#### 47.4.3.5.1 Offset

For a = 0 to 7:

| Register | Offset        |
|----------|---------------|
| CaSC     | Ch + (a × 8h) |

#### 47.4.3.5.2 Function

CnSC contains channel (n) status bits and control bits that select the channel (n) mode and its functionality.

### 47.4.3.6 Channel (n) Value (C0V - C7V)

#### 47.4.3.6.1 Offset

For a = 0 to 7:

| Register | Offset         |
|----------|----------------|
| CaV      | 10h + (a × 8h) |

### 47.4.3.6.2 Function

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture , Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writes to the CnV register are done on its write buffer. The CnV register is updated with its write buffer value according to [Registers updated from write buffers](#). If FTMEN = 0, a write to CnSC register resets manually this write coherency mechanism.

### 47.4.3.6.3 Diagram

### 47.4.3.6.4 Fields

| Field       | Function                                                                                               |

| 15-0<br>VAL | Channel Value<br>Captured FTM counter value of the input modes or the match value for the output modes |

## 47.4.3.7 Counter Initial Value (CNTIN)

### 47.4.3.7.1 Offset

| Register | Offset |
|----------|--------|
| CNTIN    | 4Ch    |

### 47.4.3.7.2 Function

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

### 47.4.3.7.4 Fields

| Field        | Function                                 |
|--------------|------------------------------------------|
| 31-16<br>—   | Reserved                                 |
| 15-0<br>INIT | INIT<br>Initial Value Of The FTM Counter |

### 47.4.3.8 Capture And Compare Status (STATUS)

### 47.4.3.8.1 Offset

| Register | Offset |
|----------|--------|
| STATUS   | 50h    |

### 47.4.3.8.2 Function

The STATUS register contains a copy of the status flag CHF bit in CnSC for each FTM channel for software convenience.

Each CHF bit in STATUS is a mirror of CHF bit in CnSC. All CHF bits can be checked using only one read of STATUS. All CHF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHF is cleared by reading STATUS while CHF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case, a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

### 47.4.3.8.3 Diagram

### 47.4.3.8.4 Fields

| Field | Function       |
|-------|----------------|
| 31-8  | Reserved       |
| —     |                |
| 7-0   | Channel n Flag |

|-------|------------------------------------------------------------------------------------------------------------|
| CHnF  | See the register description.<br>0b - No channel event has occurred.<br>1b - A channel event has occurred. |

### 47.4.3.9 Features Mode Selection (MODE)

#### 47.4.3.9.1 Offset

| Register | Offset |
|----------|--------|
| MODE     | 54h    |

#### 47.4.3.9.2 Function

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

### 47.4.3.10 Synchronization (SYNC)

#### 47.4.3.10.1 Offset

| Register | Offset |
|----------|--------|
| SYNC     | 58h    |

#### 47.4.3.10.2 Function

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CnV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

#### NOTE

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

### 47.4.3.12 Output Mask (OUTMASK)

#### 47.4.3.12.1 Offset

| Register | Offset |
|----------|--------|
| OUTMASK  | 60h    |

#### 47.4.3.12.2 Function

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

Output Mask bits must not be set for trigger mode.

#### 47.4.3.12.3 Diagram

### 47.4.3.12.4 Fields

| Field        | Function                                                                                                                                                                                                                    |

It can be written only when MODE[WPDIS] = 1.                                                                                                                                                                                                                                                                                                                                                       |

## 47.4.3.15 FTM External Trigger (EXTTRIG)

### 47.4.3.15.1 Offset

| Register | Offset |
|----------|--------|
| EXTTRIG  | 6Ch    |

### 47.4.3.15.2 Function

This register:

- Indicates when the external trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the external trigger

### 47.4.3.15.3 Diagram

### 47.4.3.16 Channels Polarity (POL)

### 47.4.3.16.1 Offset

| Register | Offset |
|----------|--------|
| POL      | 70h    |

### 47.4.3.16.2 Function

This register defines the output polarity of the FTM channels.

#### NOTE

The channel safe value is the value of its POL bit. The channel safe value is driven on the channel output when the fault control is enabled and a fault condition is detected.

### 47.4.3.16.3 Diagram

### 47.4.3.16.4 Fields

| 7-0<br>POLn | Channel n Polarity<br>Defines the polarity of the channel output.<br>This field is write protected. It can be written only when MODE[WPDIS] = 1.<br>0b - The channel polarity is active high.<br>1b - The channel polarity is active low. |

### 47.4.3.17 Fault Mode Status (FMS)

#### 47.4.3.17.1 Offset

| Register | Offset |
|----------|--------|
| FMS      | 74h    |

#### 47.4.3.17.2 Function

This register contains:

- the write protection enable bit
- the fault detection flags
- the logic OR of the enabled fault inputs

#### 47.4.3.17.3 Diagram

#### 47.4.3.17.4 Fields

| Field       | Function                                                                                                                                                                                                                                                                                                |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8<br>—   | Reserved                                                                                                                                                                                                                                                                                                |
| 7<br>FAULTF | Fault Detection Flag<br>Represents the logic OR of the FAULTF bit of each enabled fault input. Clear FAULTF by reading the FMS register while FAULTF is set and then writing a 0 to FAULTF while there is no existing fault condition at the enabled fault inputs. Writing a 1 to FAULTF has no effect. |

## 47.4.3.18 Input Capture Filter Control (FILTER)

### 47.4.3.18.1 Offset

| Register | Offset |
|----------|--------|
| FILTER   | 78h    |

### 47.4.3.18.2 Function

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

#### NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

### 47.4.3.19 Fault Control (FLTCTRL)

#### 47.4.3.19.1 Offset

| Register | Offset |
|----------|--------|
| FLTCTRL  | 7Ch    |

#### 47.4.3.19.2 Function

This register contains:

- the state of channels output when a fault event happens
- the enable for each fault input
- the filter enable for each fault input
- the filter value for enabled fault inputs and with filter

### 47.4.3.20 Quadrature Decoder Control And Status (QDCTRL)

#### 47.4.3.20.1 Offset

| Register | Offset |
|----------|--------|
| QDCTRL   | 80h    |

#### 47.4.3.20.2 Function

This register has the control and status bits for the Quadrature Decoder mode.

**NOTE**

Each module instance supports a different number of registers.

| 2<br>QUADIR | FTM Counter Direction In Quadrature Decoder Mode<br>Indicates the counting direction.<br>0b - Counting direction is decreasing (FTM counter decrement).<br>1b - Counting direction is increasing (FTM counter increment).                                                                                                                                                                                                                                                                                        |
| 1<br>TOFDIR | Timer Overflow Direction In Quadrature Decoder Mode<br>Indicates if the TOF bit was set on the top or the bottom of counting.<br>0b - TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register).<br>1b - TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register). |
| 0<br>QUADEN | Quadrature Decoder Mode Enable<br>Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes.<br>This field is write protected. It can be written only when MODE[WPDIS] = 1.<br>0b - Quadrature Decoder mode is disabled.<br>1b - Quadrature Decoder mode is enabled.                                                                                                                 |

### 47.4.3.21 Configuration (CONF)

#### 47.4.3.21.1 Offset

| Register | Offset |
|----------|--------|
| CONF     | 84h    |

#### 47.4.3.21.2 Function

This register selects the frequency of the reload opportunities, the FTM behavior in Debug mode, the use of an external global time base, and the global time base signal generation.

This register also controls if initialization trigger should be generated when a reload point is reached.

## 47.4.3.22 FTM Fault Input Polarity (FLTPOL)

### 47.4.3.22.1 Offset

| Register | Offset |
|----------|--------|
| FLTPOL   | 88h    |

### 47.4.3.22.2 Function

This register defines the fault inputs polarity.

### 47.4.3.22.3 Diagram

### 47.4.3.24 FTM Inverting Control (INVCTRL)

#### 47.4.3.24.1 Offset

| Register | Offset |
|----------|--------|
| INVCTRL  | 90h    |

#### 47.4.3.24.2 Function

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

#### 47.4.3.24.3 Diagram

#### 47.4.3.24.4 Fields

| Field | Function |
|-------|----------|
| 31-4  | Reserved |

Table continues on the next page...

| Field       | Function                                                                                      |
|-------------|-----------------------------------------------------------------------------------------------|
| —           |                                                                                               |
| 3<br>INV3EN | Pair Channels 3 Inverting Enable<br>0b - Inverting is disabled.<br>1b - Inverting is enabled. |

| 1<br>INV1EN | Pair Channels 1 Inverting Enable<br>0b - Inverting is disabled.<br>1b - Inverting is enabled. |
| 0<br>INV0EN | Pair Channels 0 Inverting Enable<br>0b - Inverting is disabled.<br>1b - Inverting is enabled. |

### 47.4.3.25 FTM Software Output Control (SWOCTRL)

#### 47.4.3.25.1 Offset

| Register | Offset |
|----------|--------|
| SWOCTRL  | 94h    |

#### 47.4.3.25.2 Function

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CH(n)OC bits enable the control of the corresponding channel (n) output by software.
- The CH(n)OCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

## 47.4.3.26 FTM PWM Load (PWMLOAD)

### 47.4.3.26.1 Offset

| Register | Offset |
|----------|--------|
| PWMLOAD  | 98h    |

### 47.4.3.26.2 Function

Enables the reload of the MOD, HCR, CNTIN, C(n)V, and C(n+1)V registers with the values of their write buffers when the FTM counter changes from the MOD register value to its next value or when a channel (j) match occurs. A match occurs for channel (j) when FTM counter = C(j)V. A reload can also occur when FTM counter = HCR register at a half cycle match. This register also controls the local and global load mechanisms.

### 47.4.3.27 Half Cycle Register (HCR)

#### 47.4.3.27.1 Offset

| Register | Offset |
|----------|--------|
| HCR      | 9Ch    |

#### 47.4.3.27.2 Function

The Half Cycle Register contains the match value for FTM half cycle reload feature. After FTM counter reaches this value, a reload opportunity is generated if FTM\_PWMLOAD[HCSEL] is enabled.

Writing to the HCR register latches the value into a buffer. The HCR register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

## 47.5 Functional Description

### 47.5.1 Clock source

The FTM has only one clock domain: the FTM input clock.

#### 47.5.1.1 Counter clock source

The CLKS[1:0] bits select one of three possible clock sources for the FTM counter or disable the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the FTM input clock or an external clock. This clock input is defined by chip integration. Refer to the chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the FTM input clock frequency.

The external clock passes through a synchronizer clocked by the FTM input clock to assure that counter transitions are properly aligned to FTM input clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the FTM input clock frequency.

## 47.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

Figure 47-7. Example of the prescaler counter

## 47.5.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder Mode](#)

### 47.5.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is  $(MOD - CNTIN + 0x0001) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

A counter event happens at the same time of TOF bit set when the FTM counter changes from MOD to CNTIN. See [Counter events](#) for more details.

FTM counting is up.  
 CNTIN = 0xFFFFC (in two's complement is equal to -4)  
 MOD = 0x0004

**Figure 47-8. Example of FTM up and signed counting**

**Table 47-3. FTM counting based on CNTIN value**

| When                             | Then                                                                                                                 |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------|
| CNTIN = 0x0000                   | The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.      |
| CNTIN[15] = 1                    | The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed. |
| CNTIN[15] = 0 and CNTIN ≠ 0x0000 | The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.                   |

## Functional Description

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

**Figure 47-9. Example of FTM up counting with CNTIN = 0x0000**

### Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

**Figure 47-10. Example of up counting when the value of CNTIN is greater than the value of MOD**

### 47.5.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (\text{MOD} - \text{CNTIN}) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

## Functional Description

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

**Figure 47-11. Example of up-down counting when CNTIN = 0x0000**

### Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if  $\text{CnV} > \text{CNTIN}$ , or
- if  $\text{CnV} = 0$  or if  $\text{CnV}[15] = 1$ . In this case, 0% CPWM is generated.

The figure below shows the possible counter events when in up-down counting mode. See [Counter events](#) for more details.

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

**Figure 47-12. Example of counter events in up-down counting mode when CNTIN = 0x0000**

### 47.5.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

A counter event occurs at the same time of TOF bit set when the FTM counter changes from 0xFFFF to 0x0000. See [Counter events](#) for more details.

**Figure 47-13. Example when the FTM counter is free running**

The FTM counter is also a free running counter when:

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

### 47.5.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).
- A channel in Input Capture mode with ICRST = 1 ([FTM Counter Reset in Input Capture Mode](#)).

Note that resetting the counter also generates a counter event. See [Counter events](#) for more details.

### 47.5.3.5 Counter events

Counter events can be used as reload opportunities to FTM register synchronization mechanism. See [Reload Points](#) for more details. There are some possible counter events depending on the counter mode. Please see the table below for more details.

**Table 47-4. FTM counter events**

| When                                                                                                                | Then                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FTM counter is in up counting mode or freerunning                                                                   | <ul style="list-style-type: none"> <li>A counter event happens at the same time of TOF bit set when the FTM counter changes from MOD to CNTIN (counter wrap). |         |          |         |       | X1      |                                  |                   | Continuous Capture mode                                                      |

**Table 47-6. Dual Edge Capture Mode — Edge Polarity Selection**

| ELSB | ELSA | Channel Port Enable | Detected Edges           |
|------|------|---------------------|--------------------------|
| 0    | 0    | Disabled            | No edge                  |
| 0    | 1    | Enabled             | Rising edge              |
| 1    | 0    | Enabled             | Falling edge             |
| 1    | 1    | Enabled             | Rising and falling edges |

### 47.5.5 Input Capture Mode

The Input Capture mode is selected when:

- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0
- CPWMS = 0
- MSB:MSA = 0:0, and
- ELSB:ELSA ≠ 0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHF bit is set and the channel interrupt is generated if enabled by CHIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSB:ELSA bits determine which edge, falling or rising, triggers input-capture event.

Writes to the CnV register are ignored in input capture mode.

While in Debug mode, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of Debug, is captured into the CnV register and the CHF bit is set.

Note: The filter is only available for the channels 0, 1, 2, and 3 inputs.

**Figure 47-14. Diagram for Input Capture Mode when FLTPS[3:0] = 0**

Note: The filter is only available for the channels 0, 1, 2, and 3 inputs.

**Figure 47-15. Diagram for Input Capture Mode when FLTPS[3:0] ≠ 0**

### 47.5.5.1 Filter for Input Capture Mode

The filter is only available on channels 0, 1, 2, and 3.

If FLTPS[3:0] = 0, the channel input after being synchronized by FTM input clock (Figure 47-14) is the filter input.

**Figure 47-16. Channel Input Filter when FLTPS[3:0] = 0**

If FLTPS[3:0]  $\neq$  0, the channel input after being synchronized by FTM input clock and being sampled by FTM filter clock (Figure 47-15) is the filter input.

**Figure 47-17. Channel Input Filter when FLTPS[3:0]  $\neq$  0**

## NOTE

The maximum frequency for the channel input to be detected correctly is FTM filter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

When there is a state change in the channel input, the counter is reset and starts counting up. As long as the new state is stable on the channel input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the new channel input signal value is validated. It is then transmitted as a pulse to the edge detector.

If the opposite edge appears on the channel input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. If a pulse is sampled as a value less than (CHnFVAL[3:0] x 4) consecutive rising edges of FTM filter clock, it is regarded as a glitch and is not passed on to the edge detector.

The table below shows the delay that is added by the FTM channel input filter according to its configuration.

**Table 47-7. FTM Channel Input Filter Delay**

| FTM channel input filter                                                                                                                                  | FLTPS[3:0] bits | Number of rising edges between the selected edge on channel input and setting CHF bit                                                                      |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>channel does not have the input filter, or</li> <li>channel input filter is disabled (CHnFVAL[3:0] = 0)</li> </ul> | FLTPS[3:0] = 0  | <ul style="list-style-type: none"> <li>3 rising edges of FTM input clock</li> </ul>                                                                        |
|                                                                                                                                                           | FLTPS[3:0] ≠ 0  | <ul style="list-style-type: none"> <li>3 rising edges of FTM input clock, plus</li> <li>1 rising edge of FTM filter clock</li> </ul>                       |
| <ul style="list-style-type: none"> <li>channel has the input filter, and</li> <li>channel input filter is enabled (CHnFVAL[3:0] ≠ 0)</li> </ul>           | FLTPS[3:0] = 0  | <ul style="list-style-type: none"> <li>(4 + 4 × CHnFVAL[3:0]) rising edges of FTM input clock</li> </ul>                                                   |
|                                                                                                                                                           | FLTPS[3:0] ≠ 0  | <ul style="list-style-type: none"> <li>4 rising edges of FTM input clock, plus</li> <li>(1 + 4 × CHnFVAL[3:0]) rising edges of FTM filter clock</li> </ul> |

The following figures illustrate two examples of channel input filter.

Note:  
 PS[2:0] = 3'b000  
 channel (n) in input capture mode with capture only on rising edges  
 CHnFVAL[3:0] = 4'h2 (channel (n) input filter is enabled)

**Figure 47-18. Example of Channel Input Filter when FLTPS[3:0] = 0**

## Functional Description

Note:  
 PS[2:0] = 3'b000  
 channel (n) in input capture mode with capture only on rising edges  
 CHnFVAL[3:0] = 4'h1 (channel (n) input filter is enabled)  
 FLTPS[3:0] = 4'h2 (divide by 3)

**Figure 47-19. Example of Channel Input Filter when FLTPS[3:0] ≠ 0**

### 47.5.5.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and CnSC[ICRST = 1], then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHF bit is set, the channel (n) interrupt is generated (if CHIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to the channel (n) input (number of the FTM input clocks) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with ICRST = 1.

**Figure 47-20. Example of the Input Capture mode with ICRST = 1**

### NOTE

- It is expected that the ICRST bit be set only when the channel is in input capture mode.
- If the FTM counter is reset because the channel is in input capture mode with ICRST = 1, then the prescaler counter ([Prescaler](#)) is also reset.

## 47.5.6 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0
- CPWMS = 0, and
- MSB:MSA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHF bit is set and the channel (n) interrupt is generated if CHIE = 1 at the channel (n) match (FTM counter = CnV).

## Functional Description

MOD = 0x0005  
CnV = 0x0003

**Figure 47-21. Example of the Output Compare mode when the match toggles the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 47-22. Example of the Output Compare mode when the match clears the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 47-23. Example of the Output Compare mode when the match sets the channel output**

If (ELSB:ELSA = 0:0) when the counter reaches the value in the CnV register, the CHF bit is set and the channel (n) interrupt is generated if CHIE = 1, however the channel (n) output is not modified and controlled by FTM.

### 47.5.7 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0

- $DECAPEN = 0$
- $MCOMBINE = 0$
- $COMBINE = 0$
- $CPWMS = 0$ , and
- $MSB = 1$

The EPWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the pulse width (duty cycle) is determined by  $(CnV - CNTIN)$ .

The CHF bit is set and the channel (n) interrupt is generated if  $CHIE = 1$  at the channel (n) match (FTM counter =  $CnV$ ), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

**Figure 47-24. EPWM period and pulse width with ELSB:ELSA = 1:0**

If (ELSB:ELSA = 0:0) when the counter reaches the value in the  $CnV$  register, the CHF bit is set and the channel (n) interrupt is generated if  $CHIE = 1$ , however the channel (n) output is not controlled by FTM.

If (ELSB:ELSA = 1:0), then the channel (n) output is forced high at the counter overflow when the  $CNTIN$  register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter =  $CnV$ ). See the following figure.

**Figure 47-25. EPWM signal with ELSB:ELSA = 1:0**

If (ELSB:ELSA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

**Figure 47-26. EPWM signal with ELSB:ELSA = X:1**

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

### Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV <= MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

## 47.5.8 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- MCOMBINE = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by  $2 \times (\text{CnV} - \text{CNTIN})$  and the period is determined by  $2 \times (\text{MOD} - \text{CNTIN})$ . See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHF bit is set and channel (n) interrupt is generated (if CHIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

**Figure 47-27. CPWM period and pulse width with ELSB:ELSA = 1:0**

If (ELSB:ELSA = 0:0) when the FTM counter reaches the value in the CnV register, the CHF bit is set and the channel (n) interrupt is generated (if CHIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSB:ELSA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

## Functional Description

MOD = 0x0008  
CnV = 0x0005

**Figure 47-28. CPWM signal with ELSB:ELSA = 1:0**

If (ELSB:ELSA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

MOD = 0x0008  
CnV = 0x0005

**Figure 47-29. CPWM signal with ELSB:ELSA = X:1**

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

## 47.5.9 Combine mode

The Combine mode is selected when:

- QUADEN = 0

- $DECAPEN = 0$
- $MCOMBINE = 0$
- $COMBINE = 1$ , and
- $CPWMS = 0$

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the PWM pulse width (duty cycle) is determined by  $(IC(n+1)V - C(n)V)$ .

The channel (n) CHF bit is set and its interrupt is generated, if channel (n)  $CHIE = 1$ , at the channel (n) match (FTM counter =  $C(n)V$ ). The channel (n+1) CHF bit is set and its interrupt is generated, if channel (n+1)  $CHIE = 1$ , at the channel (n+1) match (FTM counter =  $C(n+1)V$ ).

If channel (n)  $ELSB:ELSA = 1:0$ , then the channel (n) output is forced low at the beginning of the period (FTM counter =  $CNTIN$ ) and at the channel (n+1) match (FTM counter =  $C(n+1)V$ ). It is forced high at the channel (n) match (FTM counter =  $C(n)V$ ). See the following figure.

If channel (n)  $ELSB:ELSA = X:1$ , then the channel (n) output is forced high at the beginning of the period (FTM counter =  $CNTIN$ ) and at the channel (n+1) match (FTM counter =  $C(n+1)V$ ). It is forced low at the channel (n) match (FTM counter =  $C(n)V$ ). See the following figure.

In Combine mode, the channel (n+1)  $ELSB:ELSA$  bits are not used in the generation of the channels (n) and (n+1) output. However, if channel (n)  $ELSB:ELSA = 0:0$ , then the channel (n) output is not controlled by FTM, and if channel (n+1)  $ELSB:ELSA = 0:0$ , then the channel (n+1) output is not controlled by FTM.

**Figure 47-30. Combine mode**

The following figures illustrate the PWM signals generation using Combine mode.

**Figure 47-31. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V < C(n+1)V)$**

**Figure 47-32. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n+1)V = MOD)$**

**Figure 47-33. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 47-34. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n)V$  is Almost Equal to  $CNTIN$  and  $(C(n+1)V = MOD)$**

**Figure 47-35. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n+1)V$  is Almost Equal to  $MOD)$**

**Figure 47-46. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(C(n+1)V > MOD)$**

### 47.5.9.1 Asymmetrical PWM

In [Combine mode](#) and [Modified Combine PWM Mode](#), the PWM first edge (channel (n) match: FTM counter =  $C(n)V$ ) is independent of the PWM second edge (channel (n+1) match: FTM counter =  $C(n+1)V$ ).

### 47.5.10 Modified Combine PWM Mode

The Modified Combine PWM mode is selected when:

- $QUADEN = 0$
- $DECAPEN = 0$

- MCOMBINE = 1
- COMBINE = 1, and
- CPWMS = 0

The Modified Combine PWM mode is intended to support the generation of PWM signals where the period is not modified while the signal is being generated, but the duty cycle will be varied. In this mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output. Thus, the channel (n) match edge is fixed and the channel (n+1) match edge can be varied.

When a pair of channels is in Modified Combine PWM mode, it is recommend that the other pairs also be in Modified Combine PWM mode.

In the Modified Combine PWM mode, assuming that  $CNTIN \geq 0$ ,  $MOD > 0$ , and  $CNTIN < MOD$ :

- The PWM period is determined by  $(MOD - CNTIN + 0x0001)$ ;
- The channel (n) PWM duty cycle is calculated according to the following table.

**Table 47-8. Modified Combine PWM Mode - Duty Cycles**

| Channel (n) PWM Duty Cycle     | Condition                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0% duty cycle                  | For $CNTIN \leq (C(n)V$ and $C(n+1)V \leq MOD$ : $C(n)V = C(n+1)V$                                                                                                                                                                                                                                                            |
| duty cycle between 0% and 100% | For $CNTIN \leq (C(n)V$ and $C(n+1)V \leq MOD$ : <ul style="list-style-type: none"> <li>• if <math>(C(n)V &lt; C(n+1)V</math>), then the duty cycle is <math>(C(n+1)V - C(n)V)</math></li> <li>• if <math>(C(n)V &gt; C(n+1)V</math>), then the duty cycle is <math>[(MOD - C(n)V) + (C(n+1)V - CNTIN) + 1]</math></li> </ul> |
| 100% duty cycle                | $CNTIN \leq C(n)V \leq MOD$ and $C(n+1)V > MOD$                                                                                                                                                                                                                                                                               |

The channel (n) CHF bit is set and its interrupt is generated, if channel (n) CHIE = 1, at the channel (n) match (FTM counter =  $C(n)V$ ). The channel (n+1) CHF bit is set and its interrupt is generated, if channel (n+1) CHIE = 1, at the channel (n+1) match (FTM counter =  $C(n+1)V$ ).

If channel (n) ELSB:ELSA = 1:0, then the channel (n) output is forced high at the channel (n) match (FTM counter =  $C(n)V$ ) and it is forced low at the channel (n+1) match (FTM counter =  $C(n+1)V$ ).

If channel (n) ELSB:ELSA = X:1, then the channel (n) output is forced low at the channel (n) match (FTM counter =  $C(n)V$ ) and it is forced high at the channel (n+1) match (FTM counter =  $C(n+1)V$ ).

In Modified Combine PWM mode, the channel (n+1) ELSB:ELSA bits are not used in the generation of the channels (n) and (n+1) output. However, if channel (n) ELSB:ELSA = 0:0, then the channel (n) output is not controlled by FTM, and if channel (n+1) ELSB:ELSA = 0:0, then the channel (n+1) output is not controlled by FTM.

**Figure 47-47. Modified Combine PWM Mode**

The Modified Combine PWM mode allows the offset addition of the duty cycle, thus, in some cases, the C(n+1)V match can happen on the next FTM counter period. For  $CNTIN \geq 0$ ,  $MOD > 0$ , and  $CNTIN < MOD$ , this situation happens when  $C(n)V > C(n+1)V$ .

**Figure 47-48. Modified Combine PWM Mode Examples**

If more than one pair of channels are configured in Modified Combine PWM Mode, it is possible to fix an offset for the channel (n) match edge of each pair with respect to other pairs. This behavior is useful in the generation of lighting PWM control signals where it is desirable that edges are not coincident with each other pair to help eliminate noise generation. The C(n)V register value is the shift of the PWM pulse with respect to the beginning of FTM counter period (FTM counter = CNTIN).

**Figure 47-49. Example of Four Pairs of Channels in Modified Combine PWM Mode**

### 47.5.10.1 Synchronization

In the Modified Combine Mode, the following registers should be updated when the FTM counter clock is disabled ( $CLKS[1:0] = 0:0$ ).

- CNTIN ([CNTIN register update](#))
- MOD ([MOD and HCR registers update](#))
- C(n)V and C(n+1)V ([CnV register update](#))

In the Modified Combine Mode, if ( $FTMEN = 1$ ), ( $CLKS[1:0] \neq 0:0$ ), and there was a write to the register C(n+1)V, then the register C(n+1)V is updated with its write buffer value on the next channel (n) match (FTM counter = C(n)V). This feature allows to vary the PWM duty cycle value in this mode.

#### NOTE

In the Modified Combine Mode, the bit SYNCEN(n) should be zero bit for the channels (n) and (n+1). So, the following features are not available for this mode.

- [C\(n\)V and C\(n+1\)V register synchronization](#)
- [Reload Points](#)
- [Global Load](#)

## 47.5.11 Complementary Mode

The Complementary mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

### NOTE

The Complementary Mode is not available on [Output Compare mode](#).

The channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0
- channels (n) and (n+1) are on Combine Mode or Modified Combine PWM Mode

The channel (n+1) output is independent from channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0
- channel (n) is on Output Compare Mode, EPWM or CPWM

**Figure 47-50. Channel (n+1) output in Complementary mode with (ELSB:ELSA = 1:0)**

**Figure 47-51. Channel (n+1) output in Complementary mode with (ELSB:ELSA = X:1)**

## 47.5.12 Registers updated from write buffers

### 47.5.12.1 CNTIN register update

The following table describes when CNTIN register is updated:

**Table 47-9. CNTIN register update**

| When                                                                                                        | Then CNTIN register is updated                            |
|-------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                                             | When CNTIN register is written, independent of FTMEN bit. |
| <ul style="list-style-type: none"> <li>FTMEN = 0, or</li> <li>CNTINC = 0</li> </ul>                         | At the next FTM input clock after CNTIN was written.      |
| <ul style="list-style-type: none"> <li>FTMEN = 1,</li> <li>SYNCMODE = 1, and</li> <li>CNTINC = 1</li> </ul> | By the <a href="#">CNTIN register synchronization</a> .   |
| <ul style="list-style-type: none"> <li>CNTINC = 1, and</li> <li>LDOK = 1</li> </ul>                         | By the <a href="#">Reload Points</a> .                    |

### 47.5.12.2 MOD and HCR registers update

The following table describes when MOD or HCR registers are updated:

**Table 47-10. MOD and HCR updates**

| When                                                                                      | Then MOD or HCR is updated                              |
|-------------------------------------------------------------------------------------------|---------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                           | When MOD (or HCR) is written, independent of FTMEN bit. |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 0</li> </ul> | According to the CPWMS bit, that is:                    |

*Table continues on the next page...*

**Table 47-10. MOD and HCR updates (continued)**

| When                                                                                      | Then MOD or HCR is updated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                           | <ul style="list-style-type: none"> <li>If the selected mode is not CPWM then MOD (or HCR) is updated after MOD (or HCR) register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>If the selected mode is CPWM then MOD (or HCR) register is updated after MOD (or HCR) register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul> |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 1</li> </ul> | By the <a href="#">MOD register synchronization</a> . HCR follows the same procedure of MOD register in this case.                                                                                                                                                                                                                                                                                                                                                                                                |
| <ul style="list-style-type: none"> <li>LDOK = 1</li> </ul>                                | By the <a href="#">Reload Points</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 47.5.12.3 CnV register update

The following table describes when CnV register is updated:

**Table 47-11. CnV register update**

| When                                                                                      | Then CnV register is updated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                           | When CnV register is written, independent of FTMEN bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 0</li> </ul> | <p>According to the selected mode, that is:</p> <ul style="list-style-type: none"> <li>If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written.</li> <li>If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. | <ul style="list-style-type: none"> <li>SYNCEN = 1, and</li> <li>LDOK = 1</li> </ul>       | By the <a href="#">Reload Points</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 47.5.13 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, HCR, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

#### Note

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

#### 47.5.13.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when  $TRIGn = 1$ , where  $n = 0, 1$  or  $2$  corresponding to each one of the input signals, respectively. The hardware trigger input  $n$  is synchronized by the FTM input clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the  $TRIGn$  bit is cleared when 0 is written to it or when the trigger  $n$  event is detected.

In this case, if two or more hardware triggers are enabled (for example,  $TRIG0$  and  $TRIG1 = 1$ ) and only trigger 1 event occurs, then only  $TRIG1$  bit is cleared. If a trigger  $n$  event occurs together with a write setting  $TRIGn$  bit, then the synchronization is initiated, but  $TRIGn$  bit remains set due to the write operation.

Note  
All hardware trigger inputs have the same behavior.

**Figure 47-52. Hardware trigger event with HWTRIGMODE = 0**

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

### NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

#### 47.5.13.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Synchronization Points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

**Figure 47-53. Software trigger event**

### 47.5.13.3 Synchronization Points

The synchronization points are points where the registers can be updated with their write buffer by PWM synchronization. These synchronization points are safe points because guarantee smooth transitions in the generated PWM signals.

In **Up counting**, the synchronization points are when the FTM counter changes from MOD to CNTIN. In this case, the synchronization points are enabled if (CNTMIN = 1) or (CNTMAX = 1).

In **Up-down counting**, the synchronization points are:

- if (CNTMAX = 1), when the FTM counter changes from (MOD) to (MOD - 1);
- if (CNTMIN = 1), when the FTM counter changes from (CNTIN) to (CNTIN + 1).

**Figure 47-54. Synchronization Points**

### 47.5.13.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

## Functional Description

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

**Figure 47-55. MOD register synchronization flowchart**

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 0$ ), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the trigger enable bit ( $\text{TRIGn}$ ) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 47-56. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and software trigger was used**

**Figure 47-57. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{HWTRIGMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and a hardware trigger was used**

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 1$ ), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared according to the following example. If the trigger event was a hardware trigger, then the  $\text{TRIGn}$  bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 47-58. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used**

**Figure 47-59. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used**

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

**Figure 47-60. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)**

### 47.5.13.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

### 47.5.13.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

### 47.5.13.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of FTM input clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

**Figure 47-61. OUTMASK register synchronization flowchart**

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 47-62. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used**

**Figure 47-63. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGN bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

**Figure 47-64. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used**

### 47.5.13.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of FTM input clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 47-65. INVCTRL register synchronization flowchart

### 47.5.13.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of FTM input clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

Figure 47-66. SWOCTRL register synchronization flowchart

### 47.5.13.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

**Figure 47-67. FTM counter synchronization**

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

**Figure 47-68. FTM counter synchronization flowchart**

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 47-69. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used**

**Figure 47-70. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

**Figure 47-71. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used**

## 47.5.14 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INV<sub>m</sub> = 1 (where m represents a channel pair)

The INV<sub>m</sub> bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#).

In combine mode with channel (n) ELSB:ELSA = 1:0, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

**NOTE**

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 47-72. Channels (n) and (n+1) outputs after the inverting in combine mode with channel (n) ELSB:ELSA = 1:0**

Note that the channel (n) ELSB:ELSA bits should be considered because they define the active state of the channels outputs. In combine mode with channel (n) ELSB:ELSA = X:1, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 47-73. Channels (n) and (n+1) outputs after the inverting in combine mode with channel (n) ELSB:ELSA = X:1**

### NOTE

The Inverting is not available in [Output Compare mode](#) and [Modified Combine PWM Mode](#).

## 47.5.15 Software Output Control Mode

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CH(n)OC = 1

## Functional Description

The CH(n)OC bit enables the software output control for a specific channel output and the CH(n)OCV selects the value that is forced to this channel output.

Both CH(n)OC and CH(n)OCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE  
Channel (n) ELSB:ELSA = X:1, CH(n)OCV = 1 and CH(n+1)OCV = 0.

**Figure 47-74. Example of software output control in Combine and Complementary mode**

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

**Table 47-12. Software output control behavior when (COMP = 0)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to one        |

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

**Table 47-13. Software output control behavior when (COMP = 1)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to zero       |

### Note

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

## 47.5.16 Deadtime insertion

The deadtime insertion is enabled when DTEN is set and the concatenation {DTVALEX[3:0], DTVAL[5:0]} is non-zero.

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The clock for the DEADTIME delay is the FTM input clock divided by DTPS bits, and the {DTVALEX[3:0], DTVAL[5:0]} bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

## Functional Description

when the channel (n+1) match (FTM counter =  $C(n+1)V$ ) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n+1) output is cleared.

**Figure 47-75. Deadtime insertion with ELSB:ELSA = 1:0, POL(n) = 0, and POL(n+1) = 0**

**Figure 47-76. Deadtime insertion with ELSB:ELSA = X:1, POL(n) = 0, and POL(n+1) = 0**

### NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

## 47.5.16.1 Separated Deadtime by Pair of Channels

The separated deadtime value by pair of channels allows that each pair of channels has its own deadtime value (i.e., bits DTVALEX[3:0], DTPS[1:0], and DTVAL[5:0]).

The registers PAIR0DEADTIME, PAIR1DEADTIME, PAIR2DEADTIME, and PAIR3DEADTIME are available according to the FTM configuration.

The figure below describes how the deadtime value is defined by each pair according to the FTM configuration.

**Figure 47-77. Separated Deadtime by Pair of Channels**

The writes to the register DEADTIME also update the available registers PAIR(*j*)DEADTIME (where *j* is the pair of channels). Because of this, the write to the register DEADTIME should be done before the writes to the registers PAIR(*j*)DEADTIME.

If the pair 0 of channels has separated deadtime value, then the reads of the register DEADTIME return the read value of the register PAIR0DEADTIME. Otherwise, the read value is the value of the register DEADTIME.

## 47.5.16.2 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ( $((C(n+1)V - C(n)V) \times \text{FTM input clock})$ ), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ( $((\text{MOD} - \text{CNTIN} + 1 - (C(n+1)V - C(n)V)) \times \text{FTM input clock})$ ), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

**Figure 47-78. Example of the deadtime insertion (channel (n) ELSB:ELSA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle**

**Figure 47-79. Example of the deadtime insertion (channel (n) EL SB:EL SA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle**

### 47.5.17 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If CH(n)OM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CH(n)OM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

Functional Description

Figure 47-80. Output mask with POLn = 0

The following table shows the output mask result before the polarity control.

Table 47-14. Output mask result for channel (n) before the polarity control

| CH(n)OM | Output Mask Input | Output Mask Result |
|---------|-------------------|--------------------|
| 0       | inactive state    | inactive state     |
|         | active state      | active state       |
| 1       | inactive state    | inactive state     |
|         | active state      |                    |

47.5.18 Fault Control

The fault control is enabled if FAULTM[1:0] ≠ 0:0.

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

If FLTPS[3:0] = 0, the fault input after being synchronized by FTM input clock is the filter input.

**Figure 47-81. Diagram for Fault Control when FLTPS[3:0] = 0**

If FLTPS[3:0]  $\neq$  0, the fault input after being synchronized by FTM input clock and being sampled by FTM filter clock is the filter input.

**Figure 47-82. Diagram for Fault Control when FLTPS[3:0]  $\neq$  0**

When there is a state change in the fault input (n), the counter is reset and starts counting up. As long as the new state is stable on the fault input (n), the counter continues to increment. When the counter is equal to FFVAL[3:0] bits, the new fault input (n) value is validated. It is then transmitted as a pulse to the edge detector.

If the opposite edge appears on the fault input (n) before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. If a pulse is sampled as a value less than FFVAL[3:0] consecutive rising edges of FTM filter clock, it is regarded as a glitch and is not passed on to the edge detector.

The table below shows the delay that is added by the FTM fault input filter according to its configuration.

**Table 47-15. FTM Fault Input Filter Delay**

| FTM fault input filter                                                                                                                                                    | FLTPS[3:0] bits | Number of rising edges between the selected edge on fault input and forcing the channels outputs to their safe values                                |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>fault input does not have the input filter, or</li> <li>fault input filter is disabled (FFLTRnEN = 0 or FFVAL[3:0] = 0)</li> </ul> | FLTPS[3:0] = 0  | <ul style="list-style-type: none"> <li>3 rising edges of FTM input clock</li> </ul>                                                                  |
|                                                                                                                                                                           | FLTPS[3:0] ≠ 0  | <ul style="list-style-type: none"> <li>3 rising edges of FTM input clock, plus</li> <li>1 rising edge of FTM filter clock</li> </ul>                 |
| <ul style="list-style-type: none"> <li>fault input has the input filter, and</li> <li>fault input filter is enabled (FFLTRnEN = 1 and FFVAL[3:0] ≠ 0)</li> </ul>          | FLTPS[3:0] = 0  | <ul style="list-style-type: none"> <li>(4 + FFVAL[3:0]) rising edges of FTM input clock</li> </ul>                                                   |
|                                                                                                                                                                           | FLTPS[3:0] ≠ 0  | <ul style="list-style-type: none"> <li>4 rising edges of FTM input clock, plus</li> <li>(1 + FFVAL[3:0]) rising edges of FTM filter clock</li> </ul> |

If the fault control and fault input (n) are enabled, and the selected edge at the fault input (n) is detected, then a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

**Figure 47-83. FAULTF and FAULTIN bits and fault interrupt**

If the fault control is enabled (FAULTM[1:0] ≠ 0:0), a fault condition has occurred, and (FAULTENj = 1, where j is the pair j of the channels), then the channels (n) and (n+1) outputs are forced to their safe values:

- channel (n) output takes the POL(n) bit value
- channel (n+1) output takes the POL(n+1) bit value

The fault interrupt is generated when (FAULTF = 1) and (FAULTIE = 1). This interrupt request remains set until:

- Software clears the FAULTF bit by reading FAULTF bit as 1 and writing 0 to it
- Software clears the FAULTIE bit
- A reset occurs

### 47.5.18.1 Automatic fault clearing

If the automatic fault clearing is selected ( $\text{FAULTM}[1:0] = 1:1$ ), then the channels output disabled by fault control is again enabled when the fault input signal ( $\text{FAULTIN}$ ) returns to zero and a new PWM cycle begins. See the following figure.

**Figure 47-84. Fault control with automatic fault clearing**

### 47.5.18.2 Manual fault clearing

If the manual fault clearing is selected ( $\text{FAULTM}[1:0] = 0:1$  or  $1:0$ ), then the channels output disabled by fault control is again enabled when the  $\text{FAULTF}$  bit is cleared and a new PWM cycle begins. See the following figure.

## NOTE

The channel (n) output is after the fault control with manual fault clearing and POLn = 0.

**Figure 47-85. Fault control with manual fault clearing**

### 47.5.18.3 Fault inputs polarity control

The FLTjPOL bit selects the fault input j polarity, where j = 0, 1, 2, 3:

- If FLTjPOL = 0, the fault j input polarity is high, so the logical one at the fault input j indicates a fault.
- If FLTjPOL = 1, the fault j input polarity is low, so the logical zero at the fault input j indicates a fault.

## 47.5.19 Polarity Control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

### 47.5.20 Initialization

The initialization forces the CH(n)OI bit value to the channel (n) output when 1 is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

**Table 47-16. Initialization behavior when (COMP = 0 and DTEN = 0)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | 0         | is forced to zero  | is forced to zero    |
| 0       | 1         | is forced to zero  | is forced to one     |
| 1       | 0         | is forced to one   | is forced to zero    |
| 1       | 1         | is forced to one   | is forced to one     |

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

**Table 47-17. Initialization behavior when (COMP = 1 or DTEN = 1)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | X         | is forced to zero  | is forced to one     |
| 1       | X         | is forced to one   | is forced to zero    |

#### Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

### 47.5.21 Features Priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

Pair channels (m) - channels (n) and (n+1)

## Note:

The channels (n) and (n+1) are in Output Compare, EPWM, CPWM, Combine or Modified Combine PWM modes.

**Figure 47-86. Priority of the features used at the generation of channels (n) and (n+1) output**

## NOTE

The **Initialization** must not be used with **Inverting** and **Software Output Control Mode**.

## 47.5.22 External Trigger

If the CH(n)TRIG bit (register EXTTRIG) is set, where n = 0, 1, 2, 3, 4, 5, 6 or 7, then the FTM generates a trigger when the channel (n) match occurs (FTM counter = C(n)V) at the FTM external trigger output.

The width of a channel (n) trigger is one FTM input clock and the FTM is able to generate multiple triggers in one PWM period. See the figure below.

**Note**

- (a) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0, CH6TRIG = 0, CH7TRIG = 0
- (b) CH0TRIG = 1, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0, CH6TRIG = 0, CH7TRIG = 0
- (c) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1, CH6TRIG = 0, CH7TRIG = 0
- (d) CH0TRIG = 1, CH1TRIG = 1, CH2TRIG = 1, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1, CH6TRIG = 1, CH7TRIG = 1

**Figure 47-87. External Trigger**

### 47.5.23 Initialization Trigger

Initialization trigger allows FTM to generate a trigger in some specific points of FTM counter cycle. This feature is controlled by the bits INITTRIGEN and ITRIGR. The INITTRIGEN bit enables the initialization trigger generation and the ITRIGR bit selects when the initialization trigger is generated.

If INITTRIGEN = 1 and ITRIGR = 1, then the initialization trigger is generated when FTM counter reaches a reload point according to the frequency of the reload opportunities ([Reload Points](#)).

**NOTE**

For this configuration of initialization trigger and in CPWM mode, the bits CNTMAX and CNTMIN select where the initialization trigger is generated.

If INITTRIGEN = 1 and ITRIGR = 0, then the initialization trigger is generated when FTM counter is updated with the CNTIN register value. See the cases below.

1. When FTM counter is updated with CNTIN register value automatically.

## Functional Description

**Figure 47-88. Example of the generation of the initialization trigger in the case 1.**

2. When there is a write to CNT register.

**Figure 47-89. Example of the generation of the initialization trigger in the case 2.**

### NOTE

This behavior is not available in CPWM mode.

3. When there is the **FTM counter synchronization**.

**Figure 47-90. Example of the generation of the initialization trigger in the case 3.**

### NOTE

This behavior is not available in CPWM mode.

4. If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.

**Figure 47-91. Example of the generation of the initialization trigger in the case 4.**

### NOTE

This behavior is not available in CPWM mode.

5. If the channel (n) is in Input Capture mode, (ICRST = 1) and the selected input capture event occurs in the channel (n) input.

**Figure 47-92. Example of the generation of the initialization trigger in the case 5.**

### 47.5.24 Capture Test Mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for [Input Capture Mode](#) and FTM counter must be configured to the [Up counting](#).

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

Note:

- FTM counter is in free running
- FTMEN = 1
- FTM channel (n) is in Input Capture Mode

Figure 47-93. Capture Test Mode

### 47.5.25 DMA

The channel generates a DMA transfer request according to DMA and CHIE bits. See the following table.

**Table 47-18. Channel DMA transfer request**

| DMA | CHIE | Channel DMA Transfer Request                                | Channel Interrupt                                |
|-----|------|-------------------------------------------------------------|--------------------------------------------------|
| 0   | 0    | The channel DMA transfer request is not generated.          | The channel interrupt is not generated.          |
| 0   | 1    | The channel DMA transfer request is not generated.          | The channel interrupt is generated if (CHF = 1). |
| 1   | 0    | The channel DMA transfer request is not generated.          | The channel interrupt is not generated.          |
| 1   | 1    | The channel DMA transfer request is generated if (CHF = 1). | The channel interrupt is not generated.          |

If DMA = 1, the CHF bit is cleared either by channel DMA transfer done or reading CnSC while CHF is set and then writing a zero to CHF bit according to CHIE bit. See the following table.

**Table 47-19. Clear CHF bit when DMA = 1**

| CHIE | How CHF Bit Can Be Cleared                                                                                                           |
|------|--------------------------------------------------------------------------------------------------------------------------------------|
| 0    | CHF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHF is set and then writing a 0 to CHF bit. |
| 1    | CHF bit is cleared when the channel DMA transfer is done.                                                                            |

## 47.5.26 Dual Edge Capture Mode

The dual edge capture mode is enabled if DECAPEN = 1. This mode allows to measure a pulse width or period of the channel (n) input where n = 0, 2, 4 or 6. The channel (n) filter can be enabled for n = 0 or 2.

**Figure 47-94. Diagram for Dual Edge Capture Mode when FLTPS[3:0] = 0**

**Figure 47-95. Diagram for Dual Edge Capture Mode when FLTPS[3:0] ≠ 0**

The channel (n) MSA bit defines if the dual edge capture mode is one-shot or continuous.

The channel (n) ELSB:ELSA bits select the edge that is captured by channel (n), and channel (n+1) ELSB:ELSA bits select the edge that is captured by channel (n+1). If both channel (n) ELSB:ELSA and channel (n+1) ELSB:ELSA bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the dual edge capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then channel (n) CHF bit is set and the channel (n) interrupt is generated (if channel (n) CHIE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (channel (n) CHF = 1), then channel (n+1) CHF bit is set and the channel (n+1) interrupt is generated (if channel (n+1) CHIE = 1).

The C(n)V register stores the FTM counter value when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the FTM counter value when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism (for channels (n) and (n+1)) ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

### Note

- The dual edge capture mode must be used with channel (n) ELSB:ELSA = 0:1 or 1:0, channel (n+1) ELSB:ELSA = 0:1 or 1:0 and the FTM counter in [Free running counter](#).

### 47.5.26.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (channel (n) MSA = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The channel (n) ELSB:ELSA bits select the first edge to be captured, and channel (n+1) ELSB:ELSA bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the channel (n) CHF and channel (n+1) CHF bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the channel (n+1) CHF bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

### 47.5.26.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (channel (n) MSA = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The channel (n) ELSB:ELSA bits select the initial edge to be captured, and channel (n+1) ELSB:ELSA bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the channel (n) CHF and channel (n+1) CHF bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the channel (n+1) CHF bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the channel (n+1) CHF bit. Therefore, when the channel (n+1) CHF bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the channel (n) CHF and channel (n+1) CHF bits to start new measurements.

### 47.5.26.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (channel (n) ELSB:ELSA = 0:1) and the channel (n+1) to capture falling edges (channel (n+1) ELSB:ELSA = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (channel (n) ELSB:ELSA = 1:0) and the channel (n+1) to capture rising edges (channel (n+1) ELSB:ELSA = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The channel (n) CHF bit is set when the first edge of this pulse is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. Both DECAP and channel (n+1) CHF bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

## Note

- The commands set DECAPEN, set DECAP, clear channel (n) CHF, and clear channel (n+1) CHF are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and clear channel (n+1) CHF.
- Problem 2: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and not clear channel (n+1) CHF.

**Figure 47-96. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The channel (n) CHF bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set when the second edge of this pulse is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. The channel (n+1) CHF bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear channel (n) CHF, and clear channel (n+1) CHF are made by the user.

**Figure 47-97. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement**

#### 47.5.26.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges (channel (n) ELSB:ELSA = 0:1 and channel (n+1) ELSB:ELSA = 0:1), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges (channel (n) ELSB:ELSA = 1:0 and channel (n+1) ELSB:ELSA = 1:0), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The channel (n) CHF bit is set when the first rising edge is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. Both DECAP and channel (n+1) CHF bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

**Note**

- The commands set DECAPEN, set DECAP, clear channel (n) CHF, and clear channel (n+1) CHF are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear channel (n) CHF, and not clear channel (n+1) CHF.
- Problem 2: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and clear channel (n+1) CHF.
- Problem 3: channel (n) input = 1, set DECAP, not clear channel (n) CHF, and not clear channel (n+1) CHF.

**Figure 47-98. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The channel (n) CHF bit is set when the first rising

edge is detected, that is, the edge selected by channel (n) ELSB:ELSA bits. The channel (n+1) CHF bit is set when the second rising edge is detected, that is, the edge selected by channel (n+1) ELSB:ELSA bits. The channel (n+1) CHF bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear channel (n) CHF, and clear channel (n+1) CHF are made by the user.

**Figure 47-99. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges**

### 47.5.26.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

**Figure 47-100. Dual Edge Capture mode read coherency mechanism**

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

### 47.5.27 Quadrature Decoder Mode

The quadrature decoder mode is enabled if QUADEN = 1. The quadrature decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement.

**Figure 47-101. Diagram for Quadrature Decoder when FLTPS[3:0] = 0**

**Figure 47-102. Diagram for Quadrature Decoder when FLTPS[3:0] ≠ 0**

Each one of input signals phase A and B has a filter that is equivalent to the channel input filter ([Filter for Input Capture Mode](#)). The phase A input filter is enabled by PHAFLTREN bit and its value is defined by CH0FVAL[3:0] bits. The phase B input filter is enabled by PHBFLTREN bit and its value is defined by CH1FVAL[3:0] bits.

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in quadrature decoder mode.

### Note

The FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is enabled. Therefore it is expected that the quadrature decoder mode be used only with the FTM channels in input capture or output compare modes.

### Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the quadrature decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

**Figure 47-103. Quadrature Decoder – Count and Direction Encoding mode**

If QUADMODE = 0, then the phase A and phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;

## Functional Description

- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

**Figure 47-104. Quadrature Decoder – Phase A and Phase B Encoding Mode**

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

**Figure 47-105. FTM Counter Overflow in Up Counting for Quadrature Decoder Mode**

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

**Figure 47-106. FTM Counter Overflow in Down Counting for Quadrature Decoder Mode**

#### 47.5.27.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

## Functional Description

**Figure 47-107. Motor position jittering in a mid count value**

The following figure shows motor jittering produced by the phase B and A pulses respectively:

**Figure 47-108. Motor position jittering near maximum and minimum count value**

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

## 47.5.28 Debug mode

When the chip is in Debug mode, the BDMODE[1:0] bits select the behavior of the FTM counter, the channel (n) CHF bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

**Table 47-20. FTM behavior when the chip is in Debug mode**

| BDMODE | FTM Counter     | channel (n) CHF bit | FTM Channels Output                                                       | Writes to MOD, CNTIN, and C(n)V Registers              |
|--------|-----------------|---------------------|---------------------------------------------------------------------------|--------------------------------------------------------|
| 00     | Stopped         | can be set          | Functional mode                                                           | Writes to these registers bypass the registers buffers |
| 01     | Stopped         | is not set          | The channels outputs are forced to their safe value according to POLn bit | Writes to these registers bypass the registers buffers |
| 10     | Stopped         | is not set          | The channels outputs are frozen when the chip enters in Debug mode        | Writes to these registers bypass the registers buffers |
| 11     | Functional mode | can be set          | Functional mode                                                           | Functional mode                                        |

Note that if BDMODE[1:0] = 2'b00 then the channels outputs remain at the value when the chip enters in Debug mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this Debug mode.

- Write any value to CNT register; see [Counter reset](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see [FTM counter synchronization](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See [Initialization](#).

**Note**

The BDMMODE[1:0] = 2'b00 must not be used with the [Fault Control](#). Even if the fault control is enabled and a fault condition exists, the channels outputs are updated as above.

**Note**

If CLKS[1:0] = 2'b00 in Debug, a non-zero value is written to CLKS in Debug, and CnV = CNTIN when the Debug is disabled, then the CHF bit is set (since if the channel is a 0% EPWM signal) when the Debug is disabled.

**47.5.29 Reload Points**

This feature allows to update the registers CNTIN, HCR, MOD and C(n)V with the value of their write buffer at the selected reload point.

**NOTE**

- This feature is independent of the PWM synchronization.
- At these reload points neither the channels outputs nor the FTM counter are changed. Software must select these reload points at the safe points in time.

**47.5.29.1 Reload Opportunities**

The reload opportunities are:

1. At the half cycle

This reload opportunity is enabled if (HCSEL = 1) and it happens at the half cycle (FTM counter = HCR register). The software should calculate the half cycle value according to the FTM counter configuration, then writes this value to the register HCR.

2. At the channel (n) match

This reload opportunity is enabled if (CH(n)SEL = 1) and it happens at the channel (n) match (FTM counter = C(n)V).

3. When the FTM counter is an up counter

This reload opportunity is when the FTM counter changes from (MOD) to (CNTIN - 1) and it is always enabled.

The following figure shows an example of the reload opportunities at the half cycle, at the channels match, and when the FTM counter is an up counter.

**Figure 47-109. Reload opportunities when the FTM counter is an up counter**

#### 4. When the FTM counter is an up-down counter

In this case, the reload opportunities are enabled by the bits CNTMAX and CNTMIN according to [Table 47-21](#).

**Table 47-21. Reload opportunities enabled by the bits CNTMAX and CNTMIN when the FTM counter is up-down counter**

| CNTMAX | CNTMIN | Reload Opportunities                                                                                                                                                            |
|--------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0      | when the FTM counter changes from (MOD) to (MOD - 1)                                                                                                                            |
| 0      | 1      | when the FTM counter changes from (CNTMIN) to (CNTMIN + 1)                                                                                                                      |
| 1      | 0      | when the FTM counter changes from (MOD) to (MOD - 1)                                                                                                                            |
| 1      | 1      | <ul style="list-style-type: none"> <li>when the FTM counter changes from (MOD) to (MOD - 1), and</li> <li>when the FTM counter changes from (CNTMIN) to (CNTMIN + 1)</li> </ul> |

The following figure shows an example of the reload opportunities at the half cycle, at the channels match, and when the FTM counter is an up-down counter.

Figure 47-110. Reload opportunities when the FTM counter is an up-down counter

47.5.29.2 Frequency of Reload Opportunities

The LDFQ[4:0] bits define the number of enabled reload opportunities should happen until an enabled reload opportunity becomes a reload point. The following figure shows an example when the LDFQ[4:0] = 4.

Figure 47-111. Frequency of Reload Opportunities with LDFQ[4:0] = 4

If LDFQ[4:0] = 0, then all reload opportunities are reload points.

The counter of the reload opportunities is reset when there is a write to the register CNT.

The RF bit is set at each reload point (see the figure above) independent of LDOK bit value. The reload point interrupt is generated when (RF = 1) and (RIE = 1).

### 47.5.29.3 Update of the Registers

After writing new value to the registers with write buffer, selecting which of them will be updated (according to [Table 47-22](#)), selecting the reload opportunities, selecting the frequency of the reload opportunities, thus the LDOK bit should be set to enable the update of these registers at the next reload point.

**Table 47-22. Additional conditions to update the registers**

| Register          | Additional Condition                                            |
|-------------------|-----------------------------------------------------------------|
| CNTIN             | CNTINC = 1                                                      |
| HCR               | -                                                               |
| MOD               | -                                                               |
| C(n)V and C(n+1)V | SYNCENm = 1, where m is the pair of the channels (n) and (n +1) |

### 47.5.30 Global Load

The global load mechanism allows several modules to have their double buffered registers synchronously reloaded after a synchronization event if a write to one operation is performed in the global load OK (GLDOK) bit in the PWMLOAD register. Global load may be enabled or disabled configuring the global load enable (GLEN) bit in the PWMLOAD register. Writing one in the GLDOK bit with GLEN enabled has the same effect of writing one in the LDOK bit. Refer to SoC specific information about global load connections.

Global load mechanism allows MOD, HCR, CNTIN, and C(n)V registers to be updated with the content of the register buffer at configurable reload point. The figure below shows an example of connection between FTM global load inputs and outputs considering that GLDOK bit is implemented outside from FTM module.

**Figure 47-112. Global load logic**

### 47.5.31 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 47-113. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb\_in*, and the output signal *gtb\_out*. The GTBEEN bit enables *gtb\_in* to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when *gtb\_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb\_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb\_in* and *gtb\_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

#### NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the *gtb\_in* signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation.

The GTB feature only allows the FTM counters to *start* their operation synchronously.

### 47.5.31.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

### 47.5.32 Channel trigger output

The channel trigger output provides a trigger signal which has one FTM input clock period width in the channel (n) output.

If the TRIGMODE bit of the CnSC register is set (TRIGMODE = 1), a trigger pulse with one FTM input clock width is generated in the channel (n) output when a match occurs. It is only allowed to use trigger mode when channel (n) is in EPWM or CPWM modes.

The figures below show some cases of channel (n) trigger generation in the channel (n) output.

**Figure 47-114. Example of channel (n) trigger at the channel (n) output in EPWM mode**

## Functional Description

MOD = 0x0005  
CnV = 0x0003  
PS[2:0] = 000  
TRIGMODE = 1  
CPWM mode

**Figure 47-115. Example of channel (n) trigger at the channel (n) output in CPWM mode**

### 47.5.33 External Control of Channels Output

The channel (n) PWMEN bit can be used in an FTM external logic to control the final value of the channel (n) output. This same logic can also control the channel (n) output when FSTATE = 1 and the channel (n) output is disabled by the Fault Control. The following figure shows an example of this external logic.

The term "channel (n) output" means the channel (n) output value after the Polarity Control. See [Features Priority](#) and [Polarity Control](#) for more details.

**Figure 47-116. Example of the External Control of the Channel (n) Output**

### 47.5.34 Dithering

FTM implements a fractional delay to achieve fine resolution on the generated PWM signals using dithering. The dithering can be used by applications where more resolution than one unit of the FTM counter is needed.

Two kinds of dithering are available: PWM period dithering and edge dithering.

### 47.5.34.1 PWM Period Dithering

The PWM period dithering is enabled when a non-zero value is written to FRACMOD.

The internal accumulator used in the PWM period dithering is reset when:

- the field MOD of the register MOD\_MIRROR is updated with the value of its write buffer,
- the FRACMOD is updated with the value of its write buffer, or
- the FTM counter is stopped.

#### NOTE

For the PWM period dithering, the register MOD\_MIRROR should be used instead of the register MOD.

To avoid inconsistencies, the field FRACMOD is cleared when the field MOD of the register MOD is updated with the value of its write buffer.

The PWM period dithering is not available:

- when the FTM counter is a free running counter
- when the FTM is in quadrature decoder mode

#### 47.5.34.1.1 Up Counting

When the FTM counter is an up counter and the PWM period dithering is enabled, at the end of each PWM period, the FRACMOD value is added to an internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), then one unit of FTM counter is added to the end of the current PWM period, and the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

Due to one unit of FTM counter that can be added to the PWM period, the largest valid value for MOD is 0xFFFFE for PWM period dithering with unsigned counting and 0x7FFE for PWM period dithering with signed counting.

The following figures show some examples of PWM period dithering when the FTM counter is an up counter.

**Figure 47-117. PWM Period Dithering with Up Counting**

Assuming:

- the FTM counter is an up counter,
- T is one unit of FTM counter,
- the PWM period without period dithering is  $[(MOD - CNTIN + 1) \times T]$ ,
- the number of PWM periods with period dithering is FRACMOD,
- the PWM period with period dithering is  $[(MOD - CNTIN + 1 + 1) \times T]$ ,

thus, the average period (in decimal) is  $[(MOD - CNTIN + 1) + (FRACMOD/32)] \times T$ , where the integer value is  $(MOD - CNTIN + 1)$  and the fractional value is  $(FRACMOD/32)$ . See the example below.

**Figure 47-118. Example of Average Period when the PWM Period Dithering is used with the Up Counting**

**NOTE**

For the generation of 100% PWM signal in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using EPWM mode and PWM Period Dithering, it is recommended to use  $(C(n) > MOD + 1)$ .

For the generation of PWM signals in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Period Dithering, it is recommended to use:

- For 0% PWM signal:  $(C(n)V > MOD + 1)$  and  $(C(n+1)V > MOD + 1)$ ;
- For 100% PWM signal:  $(C(n)V = CNTIN)$  and  $(C(n+1)V > MOD + 1)$ .

For the generation of PWM signals in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Period Dithering, it is recommended to use:

- For 0% PWM signal:  $(C(n)V > MOD + 1)$  and  $(CNTIN \leq C(n+1)V \leq MOD)$ ;
- For 100% PWM signal:  $(CNTIN \leq C(n)V \leq MOD)$  and  $(C(n+1)V > MOD + 1)$ .

**47.5.34.1.2 Up-Down Counting**

When the FTM counter is an up-down counter and the PWM period dithering is enabled, at the end of each PWM period, the FRACMOD value is added to an internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), then one unit of FTM counter is added to the end of the current PWM period and other unit is added to the begin of the next PWM period (see the figure below). After the accumulator overflows, the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

Due to one unit of FTM counter that can be added to the PWM period, the largest valid value for MOD is 0x7FFE for PWM period dithering in up-down counting (CPWM mode).

**Figure 47-119. PWM Period Dithering with Up-Down Counting**

### NOTE

For the generation of 100% PWM signal in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using CPWM mode and PWM Period Dithering, it is recommended to use (C(n)V[15] = 0) and (C(n)V > MOD + 1) and (MOD ≠ 0x0000).

#### 47.5.34.2 PWM Edge Dithering

The channel (n) internal accumulator used in the PWM edge dithering is reset when:

- the field VAL of the register C(n)V\_MIRROR is updated with the value of its write buffer,
- the FRACVAL is updated with the value of its write buffer, or
- the FTM counter is stopped.

### NOTE

For the PWM edge dithering, the register C(n)V\_MIRROR should be used instead of the register C(n)V.

To avoid inconsistencies, the field FRACVAL is cleared when the field VAL of the register C(n)V is updated with the value of its write buffer.

The PWM edge dithering is not available:

- to the channel in input modes, and
- to the channel in output compare mode.

### 47.5.34.2.1 EPWM Mode

The PWM edge dithering for channel (n) in EPWM mode is enabled when a non-zero value is written to the channel (n) FRACVAL.

If the channel (n) is in EPWM mode and the PWM edge dithering is enabled, at the end of each EPWM period, the channel (n) FRACVAL value is added to the channel (n) internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

In this configuration, the initial edge of EPWM duty cycle happens when (FTM counter = CNTIN), its position is not modified by the PWM edge dithering. If there was not the overflow of the channel (n) accumulator in the current EPWM period, then the final edge of EPWM duty cycle happens on the channel (n) match (FTM counter = C(n)V), that is, its position is not modified by the edge dithering. However, if there was the overflow of the channel (n) accumulator in the current EPWM period, then the final edge of EPWM duty cycle happens when (FTM counter = C(n)V + 0x0001).

The following figures show some examples of PWM edge dithering when the channel (n) is in EPWM mode.

**Figure 47-120. Channel (n) is in EPWM Mode with PWM Edge Dithering**

Assuming:

## Functional Description

- the channel (n) is in EPWM mode,
- T is one unit of FTM counter,
- the EPWM duty cycle without edge dithering is  $[(C(n)V - CNTIN) \times T]$ ,
- the number of PWM periods which duty cycle that has edge dithering is FRACVAL,
- the EWM duty cycle with edge dithering is  $[(C(n)V - CNTIN + 1) \times T]$ ,

thus, the average duty cycle (in decimal) is  $[(C(n)V - CNTIN) + (FRACVAL/32)] \times T$ , where the integer value is  $(C(n)V - CNTIN)$  and the fractional value is  $(FRACVAL/32)$ . See the example below.

**Figure 47-121. Example of Average Duty Cycle when the Channel (n) is in EPWM Mode with PWM Edge Dithering**

### 47.5.34.2.2 CPWM Mode

The PWM edge dithering for channel (n) in CPWM mode is enabled when a non-zero value is written to the channel (n) FRACVAL.

If the channel (n) is in CPWM mode and the PWM edge dithering is enabled, at the end of each CPWM period, the channel (n) FRACVAL value is added to the channel (n) internal 5-bit accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

In this configuration, if there was not the overflow of the channel (n) accumulator in the current CPWM period, then the duty cycle is not modified by the PWM edge dithering, that is, the initial edge of CPWM duty cycle happens on channel (n) match (FTM counter = C(n)V) when the FTM counter is decrementing, and the final edge of CPWM duty cycle on channel (n) match when the FTM counter is incrementing.

However, if there was the overflow of the channel (n) accumulator in the current CPWM period, then the initial edge of CPWM duty cycle happens when (FTM counter =  $C(n)V + 0x0001$ ) and the FTM counter is decrementing, and the final edge of CPWM duty cycle when (FTM counter =  $C(n)V + 0x0001$ ) and the FTM counter is incrementing.

The following figure shows an example of PWM edge dithering when the channel (n) is in CPWM mode.

**Figure 47-122. Channel (n) is in CPWM Mode with PWM Edge Dithering**

#### 47.5.34.2.3 Combine Mode

In the Combine mode, the PWM edge dithering can be done:

- in the channel (n) match (FTM counter =  $C(n)V$ ) edge or
- in the channel (n+1) match (FTM counter =  $C(n+1)V$ ) edge.

The channel (n) match edge dithering is enabled when a non-zero value is written to the channel (n) FRACVAL.

For the channel (n) match edge dithering, the channel (n) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n) FRACVAL value is added to the channel (n) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n) accumulator in the current PWM period, the channel (n) match edge is not modified, that is, it happens on channel (n) match. However, if there was the overflow of the channel (n) accumulator, the channel (n) match edge happens when (FTM counter =  $C(n)V + 0x0001$ ).

The following figure shows an example of the channel (n) match edge dithering when the channels (n) and (n+1) are in Combine mode.

**Figure 47-123. Channel (n) Match Edge Dithering in Combine Mode**

The channel (n+1) match edge dithering is enabled when a non-zero value is written to the channel (n+1) FRACVAL.

For the channel (n+1) match edge dithering, the channel (n+1) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n+1) FRACVAL value is added to the channel (n+1) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n+1) accumulator in the current PWM period, the channel (n+1) match edge is not modified, that is, it happens on channel (n+1) match. However, if there was the overflow of the channel (n+1) accumulator, the channel (n+1) match edge happens when (FTM counter = C(n+1)V + 0x0001).

The following figure shows an example of the channel (n+1) match edge dithering when the channels (n) and (n+1) are in Combine mode.

**Figure 47-124. Channel (n+1) Match Edge Dithering in Combine Mode**

## NOTE

It is recommended to use only one PWM Edge Dithering (channel (n) PWM Edge Dithering or channel (n+1) PWM Edge Dithering) at a time.

For the generation of 0% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Edge Dithering, it is recommended to use:

- (C(n)V < CNTIN or C(n)V > MOD) and (channel (n) FRACVAL is zero) and
- (channel (n+1) FRACVAL is zero).

For the generation of 100% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Combine mode and PWM Edge Dithering, it is recommended to use:

- (C(n)V = CNTIN) and (channel (n) FRACVAL is zero) and
- (C(n+1)V < CNTIN or C(n+1)V > MOD) and (channel (n+1) FRACVAL is zero).

### 47.5.34.2.4 Modified Combine PWM Mode

In the Modified Combine PWM mode, the PWM edge dithering can be done:

- in the channel (n) match (FTM counter = C(n)V) edge or
- in the channel (n+1) match (FTM counter = C(n+1)V) edge.

The channel (n) match edge dithering is enabled when a non-zero value is written to the channel (n) FRACVAL.

For the channel (n) match edge dithering, the channel (n) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n) FRACVAL value is added to the channel (n) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n) accumulator in the current PWM period, the channel (n) match edge is not modified, that is, it happens on channel (n) match. However, if there was the overflow of the channel (n) accumulator, the channel (n) match edge happens when (FTM counter = C(n)V + 0x0001).

The following figure shows an example of the channel (n) match edge dithering when the channels (n) and (n+1) are in Modified Combine PWM mode.

**Figure 47-125. Channel (n) Match Edge Dithering in Modified Combine PWM Mode**

The channel (n+1) match edge dithering is enabled when a non-zero value is written to the channel (n+1) FRACVAL.

For the channel (n+1) match edge dithering, the channel (n+1) has an internal 5-bit accumulator. At the end of each PWM period, the channel (n+1) FRACVAL value is added to the channel (n+1) accumulator. When this accumulator overflows (that is, the result of the adding is greater or equal than 0x20), the accumulator remains with the rest of the subtraction: (the result of this adding - 0x20).

If there was not the overflow of the channel (n+1) accumulator in the current PWM period, the channel (n+1) match edge is not modified, that is, it happens on channel (n+1) match. However, if there was the overflow of the channel (n+1) accumulator, the channel (n+1) match edge happens when (FTM counter = C(n+1)V + 0x0001).

The following figure shows an example of the channel (n+1) match edge dithering when the channels (n) and (n+1) are in Modified Combine PWM mode.

**Figure 47-126. Channel (n+1) Match Edge Dithering in Modified Combine PWM Mode**

## NOTE

It is recommended to use only one PWM Edge Dithering (channel (n) PWM Edge Dithering or channel (n+1) PWM Edge Dithering) at a time.

For the generation of 0% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Edge Dithering, it is recommended to use:

- $(C(n)V < CNTIN \text{ or } C(n)V > MOD)$  and (channel (n) FRACVAL is zero) and
- $(CNTIN \leq C(n+1)V \leq MOD)$  and (channel (n+1) FRACVAL is zero).

For the generation of 100% PWM in the channel (n) (with channel (n) ELSB:ELSA = 2'b10) using Modified Combine PWM mode and PWM Edge Dithering, it is recommended to use:

- $(CNTIN \leq C(n)V \leq MOD)$  and (channel (n) FRACVAL is zero) and
- $(C(n+1)V < CNTIN \text{ or } C(n+1)V > MOD)$  and (channel (n+1) FRACVAL is zero).

## 47.6 Reset Overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 2'b00);
- the timer overflow interrupt is zero ([Timer Overflow Interrupt](#));
- the channels interrupts are zero ([Channel \(n\) Interrupt](#));
- the fault interrupt is zero ([Fault Interrupt](#));
- the channels are in input capture mode ([Input Capture Mode](#));
- the channels outputs are zero;
- the channels ELSB:ELSA = 0:0 ([Channel Modes](#)) and PWMEN = 0 ([External Control of Channels Output](#)).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (CLKS[1:0] = 2'b00), its value is updated to zero and the pins are not controlled by FTM ([Channel Modes](#)).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero.

**Figure 47-127. FTM behavior after reset when the channel (n) is in Combine mode**

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software Output Control Mode](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

**Figure 47-128. FTM behavior after reset when the channel (n) is in Output Compare mode**

## 47.7 FTM Interrupts

### 47.7.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 47.7.2 Reload Point Interrupt

The Reload Point interrupt is generated when (RIE = 1) and (RF = 1).

### 47.7.3 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHIE = 1) and (CHF = 1).

### 47.7.4 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

## 47.8 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer. This procedure can also be used to do a new configuration.

1. Define the POL bits.
2. Mask the channels outputs using `SYNCHOM = 0`. Two clocks after the write to `OUTMASK`, the channels outputs are in the safe value.
3. (Re)Configuration FTM counter and channels to generation of periodic signals:
  - a. Disable the clock. Disable the Quadrature Decoder mode.
  - b. Examples of (re)configuration:
    - Write to `MOD`
    - Write to `CNTIN`
    - Configure the channels that will be used
    - Write to `CnV` for the channels in output modes
    - (Re)Configure deadtime and fault control
    - Do not use the `SWOC` without `SW` synchronization (see item 6)
    - Do not use the Inverting without `SW` synchronization (see item 6)
    - Do not use the Initialization
    - Do not change the polarity control
    - Do not configure the `HW` synchronization
4. Write any value to `CNT`. The FTM Counter is reset and the channels outputs are updated according to new configuration.
5. Enable the clock. Write to `CLKS[1:0]` bits a value different from zero. Enable the Quadrature Decoder mode (if it is desired).
6. Configure the `SW` synchronization for `SWOC` (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - a. Select synchronization for Output Mask
    - Write to `SYNC` (`SWSYNC = 0`, `TRIG2 = 0`, `TRIG1 = 0`, `TRIG0 = 0`, `SYNCHOM = 1`, `REINIT = 0`, `CNTMAX = 0`, `CNTMIN = 0`)
  - b. Write to `SYNCONF`
    - `HW` Synchronization can not be enabled (`HWSOC = 0`, `HWINVC = 0`, `HWOM = 0`, `HWWRBUF = 0`, `HWRSTCNT = 0`, `HWTRIGMODE = 0`)
    - `SW` Synchronization for `SWOC` (if it is necessary): `SWSOC = [0/1]` and `SWOC = [0/1]`
    - `SW` Synchronization for Inverting (if it is necessary): `SWINVC = [0/1]` and `INVC = [0/1]`
    - `SW` Synchronization for `SWOM` (always): `SWOM = 1`

- No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using  $CLKS[1:0] = 2'b00$ ):  $SWWRBUF = 0$  and  $CNTINC = 0$
  - SW Synchronization for counter reset (always):  $SWRSTCNT = 1$
  - Enhanced synchronization (always):  $SYNCMODE = 1$
- c. If the SWOC is used ( $SWSOC = 1$  and  $SWOC = 1$ ), then write to  $SWOCTRL$  register.
  - d. If the Inverting is used ( $SWINVC = 1$  and  $INVC = 1$ ), then write to  $INVCTRL$  register.
  - e. Write to  $OUTMASK$  to enable the masked channels.
7. Generate the Software Trigger
    - Write to  $SYNC$  ( $SWSYNC = 1$ ,  $TRIG2 = 0$ ,  $TRIG1 = 0$ ,  $TRIG0 = 0$ ,  $SYNCHOM = 1$ ,  $REINIT = 0$ ,  $CNTMAX = 0$ ,  $CNTMIN = 0$ )
  8. Configure  $PWMEN$  bits ([External Control of Channels Output](#)).

# Chapter 48

## Low Power Interrupt Timer (LPIT)

### 48.1 Chip-specific LPIT information

#### 48.1.1 Instantiation Information

S32K1xx contains one LPIT module with four channels. Low leakage mode and Wait mode is not supported in this device. See [Module operation in available power modes](#) for details on available power modes.

Accessing LPIT when its functional clock is disabled may give transfer error.

#### 48.1.2 LPIT/DMA Periodic Trigger Assignments

The LPIT generates periodic trigger events to the DMAMUX as shown in the table below.

**Table 48-1. LPIT channel assignments for periodic DMA triggering**

| DMA Channel Number | LPIT Channel |
|--------------------|--------------|
| 0                  | 0            |
| 1                  | 1            |
| 2                  | 2            |
| 3                  | 3            |

### 48.1.3 LPIT input triggers

LPIT is designed to capture small pulses at its input trigger irrespective of its clock frequency as mentioned in S32K14x\_Trigger\_Muxing.xlsx attached to the Reference manual. But for reliable back to back operation these triggers should be spaced apart by at least 10 LPIT bus clock cycles.

### 48.1.4 LPIT/ADC Trigger

The LPIT could be used as an alternate ADC hardware trigger source, the implementation is through TRGMUX. Each LPIT channel supports one pre-trigger and one trigger. The LPIT channels are implemented based on independent counters. When used as ADC trigger source, the channel outputs generate the ADC hardware triggers and pre-triggers. The following diagram shows an example of using LPIT triggering ADC0.

The LPIT triggers can also have multiple sources. Refer to [ADC Trigger Sources](#).

\* The block depicts simplified schematic and doesn't show detailed latching. See section 'Trigger Latching and Arbitration' of ADC chapter for details

**Figure 48-1. ADC triggering scheme**

### 48.1.5 Current timer value

Following table describes the Current Timer Value register reads across devices.

**Table 48-2. Current Timer Value register reads**

| S32K1xx devices                                                                                                                                                        | S32K14xW devices                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| While the timer is running, CVALn register reads may not return the real value. If the timer value needs to be read, read it during an LPIT interrupt service routine. | CVALn register reads return the real value even if timer is running |

## 48.1.6 S32K11X to S32K14X difference

See [Differences between S32K14x/S32K14xW, and S32K11x](#), for differences arising out of CPU and interrupt latency impacting timed events when comparing S32K14X and S32K11X variants.

## 48.2 Introduction

### 48.2.1 Overview

LPIT is a low power periodic interrupt timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channel will generate pre-trigger and trigger output signals, and these pre-trigger and trigger outputs can be used to trigger other modules on the device.

- Timers can be configured to be controlled using:
  - external triggers (triggers from outside the LPIT module)
  - or internal triggers (triggers from other timer channels inside the LPIT module).
- The timer channels can be chained together, to form a larger width timer.
- Depending on the timer modes, the timer channels may reload and count again, or stop after reaching the programmed count.

The next figure shows the interface of an LPIT module to the other modules on the SoC.

- The CPU interface provides the clock, reset, register read/write bus interface and handles interrupts from an LPIT.
- The trigger output signals from an LPIT may trigger other modules on the SoC, like the DMA, ADC, and other modules.
- Similarly, other timer modules may provide trigger inputs to an LPIT module, to control when an LPIT timer channel starts.

For the exact module interactions, see the SoC Configuration chapter in your device's hardware Reference Manual (RM).

Figure 48-2. LPIT Interface in SoC

Each timer channel in LPIT can be configured to work in either compare modes or capture modes.

- **In compare mode:** the timers decrement when enabled and generate an output pre-trigger and trigger output. The trigger output is 1 clock cycle delayed of the pre-trigger pulse. Each timer channel start, reload and restart can be controlled via control bits. The timer can be configured to always decrement from a programmed start value, or decrement on selected trigger inputs or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.
- **In capture mode:** the timer can be used to perform measurements as the timer value is captured (in the timer value register) when a selected trigger input is asserted. The timer can support once-off or multiple measurements (like frequency measurements).

The timer channels operate on an asynchronous clock, which is independent from the register read/write access clock. Clock synchronization between the clock domains ensures normal operations.

### 48.2.2 Block Diagram

The next figure shows a detailed block diagram for an LPIT module. The programming model comprises of a global register set (common to all timer channels), and registers for each timer channel (that control their respective timer channels). Access to these registers gets synchronized to the asynchronous peripheral clock, then affects the timer channel registers.

## Modes of operation

- Each timer channel contains a 32-bit counter that loads the starting value and down counts on every peripheral clock's positive edge.
- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- The counter enable is controlled using a timer enable register control bit, external or internal triggers or via previous channel timeout (when using timer chaining).
- After a channel timer timeout, an interrupt bit is also set, to tell the CPU about the timer timeout.

For more details, see the functional description section.

Figure 48-3. Detailed Block Diagram

## 48.3 Modes of operation

The LPIT module supports the following chip modes.

**Table 48-3. Chip modes supported by the LPIT module**

| Chip mode | LPIT Operation                                                                                                                                                           |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Run       | Normal operation                                                                                                                                                         |
| Stop      | Can continue operating, if the Doze Enable bit (MCR[DOZE_EN]) is set and the LPIT is using an external or internal clock source that remains operating during stop mode. |
| Debug     | Can continue operating provided the Debug Enable bit (MCR[DBG_EN]) is set.                                                                                               |

## 48.4 Memory Map and Registers

### 48.4.1 LPIT register descriptions

The memory map comprises of 32-bit aligned registers, which can be accessed via 8-bit, 16-bit, or 32-bit accesses.

- Write access to reserved locations will generate a transfer error.
- Read access to reserved locations will also generate a transfer error, and the read data bus will show all 0s.

#### NOTE

- The Memory Map and complete module is in Big Endian format.
- The LPIT module will not check if programmed values in the registers are correct; software must ensure that correct programmed values are being written.

#### 48.4.1.1 LPIT memory map

LPIT base address: 4003\_7000h

| Offset | Register                                                | Width<br>(In bits) | Access | Reset value |

### 48.4.1.7 Set Timer Enable Register (SETTEN)

#### 48.4.1.7.1 Offset

| Register | Offset |
|----------|--------|
| SETTEN   | 14h    |

#### 48.4.1.7.2 Function

The Set Timer Enable register allows the simultaneous enabling of timer channels.

- Timer channels can be enabled by
  - either by writing '1' to Timer Enable bit (T\_EN) in the respective TCTRLn register,
  - or by setting the corresponding Set Timer Enable bit (SET\_T\_EN\_n) in the Set Timer Enable register (SETTEN).

- To disable timer channels simultaneously, use the Clear Timer Enable register (CLR TEN).
- Writing a '0' to the Set Timer Enable register has no effect.

**NOTE**

Unless the Module Clock Enable bit (MCR[M\_CEN]) is set (=1, peripheral clock to timers is enabled), reading or writing the Set Timer Enable register will generate a transfer error.

## 48.4.1.8 Clear Timer Enable Register (CLRTEEN)

### 48.4.1.8.1 Offset

| Register | Offset |
|----------|--------|
| CLRTEEN  | 18h    |

### 48.4.1.8.2 Function

#### NOTE

Unless the Module Clock Enable bit (MCR[M\_CEN]) is set (=1, peripheral clock to timers is enabled), reading or writing the Clear Timer Enable register will generate a transfer error.

### 48.4.1.9 Timer Value Register (TVAL0 - TVAL3)

#### 48.4.1.9.1 Offset

| Register | Offset |
|----------|--------|
| TVAL0    | 20h    |
| TVAL1    | 30h    |
| TVAL2    | 40h    |
| TVAL3    | 50h    |

#### 48.4.1.9.2 Function

- In compare modes: the Timer Value Registers (TVAL $n$ ) select the timeout period for the timer channels.
- In capture modes: the Timer Value Registers (TVAL $n$ ) are loaded with the value of the counter when the trigger asserts.

#### NOTE

Unless the Module Clock Enable bit (MCR[M\_CEN]) is set (=1, peripheral clock to timers is enabled), then reading or writing the TVAL $n$  register will generate a transfer error.

| Field       | Function                                                     |
|-------------|--------------------------------------------------------------|
| 31-0        | Current Timer Value                                          |
| TMR_CUR_VAL | Represents the current timer value, if the timer is enabled. |

## 48.4.1.11 Timer Control Register (TCTRL0 - TCTRL3)

### 48.4.1.11.1 Offset

| Register | Offset |
|----------|--------|
| TCTRL0   | 28h    |
| TCTRL1   | 38h    |
| TCTRL2   | 48h    |
| TCTRL3   | 58h    |

### 48.4.1.11.2 Function

The Timer Control registers contain the control bits for each timer channel.

#### NOTE

- Unless the peripheral clock to the timers is enabled (Module Clock Enable bit (MCR[M\_CEN]) is set (=1)),

then reading or writing the Timer Control register will generate a transfer error.

- Timer controls should only be updated when the timer is disabled. In the Timer Control Register TCTRLn, these timer controls include:
  - Trigger Select TRG\_SEL
  - Trigger Source TRG\_SRC
  - Timer Reload On Trigger TROT
  - Timer Stop On Interrupt TSOI
  - Timer Start On Trigger TSOT
  - Timer Operation Mode MODE
  - Chain Channel CHAIN

There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLR\_TEN[CLR\_T\_EN\_n]) or set the timer enable bit (TCTRLn[T\_EN]) = 0 for that channel.

The MODE bits control how the timer decrements.<br>00b - 32-bit Periodic Counter<br>01b - Dual 16-bit Periodic Counter<br>10b - 32-bit Trigger Accumulator<br>11b - 32-bit Trigger Input Capture                                                                                                                                                                                                                                                                                                                              |
| 1<br>CHAIN    | Chain Channel<br>When enabled, the timer channel will decrement when timer channel N-1 trigger asserts. Timer channel 0 cannot be chained.<br>0b - Channel Chaining is disabled. The channel timer runs independently.<br>1b - Channel Chaining is enabled. The timer decrements on the previous channel's timeout.                                                                                                                                                                                                                                                                                     |
| 0<br>T_EN     | Timer Enable<br>Enables or disables the Timer Channel<br>0b - Timer Channel is disabled<br>1b - Timer Channel is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 48.5 Functional description

### 48.5.1 LPIT programming model

**Figure 48-4. Programming Model**

Global registers need only be set once:

- Version ID Register (VERID)
- Parameter Register (PARAM)
- Module Control Register (MCR)
- Module Status Register (MSR)
- Module Interrupt Enable Register (MIER)

## Functional description

- Set Timer Enable Register (SETTEN)
- Clear Timer Enable Register (CLR TEN)

Channel registers must be set for each channel:

- Timer Value Register (TVAL0 - TVAL3)
- Current Timer Value (CVAL0 - CVAL3)
- Timer Control Register (TCTRL0 - TCTRL3)

## 48.5.2 Initialization

**Table 48-4. Initializing the LPIT module**

| Step |                                               | How? Why?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

When enabling the clock to this module, ensure that software is configuring those additional clock gating bits (in addition to M_CEN bit).</li></ul> |
| 2    | Wait for 4 peripheral clock cycles            | to allow time for clock synchronization and reset de-assertion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3    | Configure timer control bits                  | for each timer channel that is to be enabled: <ul style="list-style-type: none"><li>• timer mode of operation bits TCTRLn[MODE]</li><li>• trigger source selection bits TCTRLn[TRG_SEL, TRG_SRC]</li><li>• trigger control bits TCTRLn[TROT, TSOT, TSOI]</li></ul><br><b>NOTE:</b> Timer controls should only be updated when the timer is disabled. There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLRTEN[CLR_T_EN_n]) or set the timer enable bit (TCTRLn[T_EN]) = 0 for that channel.                                                                                                                                                                    |
| 4    | Configure the channels that are to be chained | by setting the CHAIN bit in the corresponding channel's TCTRLn register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5    | Set the timer timeout value                   | for channels configured in Compare Mode, by programming the appropriate value in TVAL register for those channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6    | Configure TIEN bits in MIER register          | for those channels that are required to generate interrupts on timer timeouts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 7    | Configure the low power modes of the module   | by setting the DBG_EN and DOZE_EN bits in the MCR register. This is common to all timer channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 8    | Enable the channel timers                     | by setting the corresponding T_EN bit in the corresponding channel's TCTRLn register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

*Also:*

- For channels configured in Capture Mode, the timer value can be read from TVALn register when a channel timeout occurs.
- At any time, the current value of the timer for any channel can be read by reading the corresponding channel's CVALn register. The M\_CEN bit must be '1' when doing so.
- The timer interrupt flag bits (TIFn) in MSR register get asserted on timer timeout. To clear these timer interrupt flag bits, write '1' to them.

### 48.5.3 Timer Modes

The timer mode is configured by setting an appropriate value in the MODE bits in TCTRLn register.

**Table 48-5. Timer modes that are supported**

| Timer Mode                   | Operation                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 32-bit Periodic Counter      | <ul style="list-style-type: none"> <li>• The counter will load, decrement down to 0</li> <li>• which will set the timer interrupt flag and assert the output pre-trigger.</li> </ul>                                                                                                                                                                                                                         |
| Dual 16-bit Periodic Counter | <ul style="list-style-type: none"> <li>• The counter will load, then the lower 16-bits will decrement down to 0</li> <li>• which will assert the output pre-trigger.</li> <li>• The upper 16-bits will then decrement down to 0</li> <li>• which will set the timer interrupt flag and then negate the output pre-trigger.</li> </ul>                                                                        |
| 32-bit Trigger Accumulator   | <ul style="list-style-type: none"> <li>• The counter will load on the 1st trigger rising edge and then decrement down to 0 on each trigger rising edge</li> <li>• which will set the timer interrupt flag and assert the output pre-trigger.</li> </ul>                                                                                                                                                      |
| 32-bit Trigger Input Capture | <ul style="list-style-type: none"> <li>• The counter will load with 0xFFFF_FFFF and then decrement down to 0.</li> <li>• If a trigger rising edge is detected, <ul style="list-style-type: none"> <li>• then it will store the inverse of the current counter value in the timer value register</li> <li>• which will set the timer interrupt flag and assert the output pre-trigger.</li> </ul> </li> </ul> |

The timer operation is controlled by Trigger Control bits (TSOT, TSOI, TROT) which control the timer load, reload, start and restart of the timers.

#### NOTE

- The trigger output is asserted one Peripheral Timer Clock cycle later than pre-trigger output. The trigger output and the pre-trigger output de-assert at the same time.
- The pre-trigger output is asserted for 2 clock cycles and the trigger output is asserted for 1 clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger are asserted for many cycles depending on TMR\_VAL[31:16]).
- Timer changes *that are based on external triggers* take effect after 4 peripheral clocks after the actual external

trigger assertion (due to clock synchronization, rise edge detection and timer update).

## 48.5.4 Trigger Control for Timers

Various programmable bits control how the trigger inputs and the timer operate.

TRG\_SEL and TRG\_SRC select the timer triggers:

- Trigger Select (TRG\_SEL) selects the input trigger for the channel from all of the other channel's trigger outputs.
- Trigger Source (TRG\_SRC) selects between the internal trigger and the external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of the TROT, TSOI and TSOT bits.

**Table 48-6. How bits control timer operations**

| If                                     | = | Then                                                                                                                                                                                                                                  |
|----------------------------------------|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TSOI<br><i>Timer Stop On Interrupt</i> | 1 | then the counter stops on a Timer Interrupt flag (MSR[TIFn]) assertion. To reload and decrement, it requires: <ul style="list-style-type: none"> <li>• a trigger (if TSOT = 1)</li> <li>• a T_EN rising edge (if TSOT = 0)</li> </ul> |
|                                        | 0 | then the counter does not stop after timeout                                                                                                                                                                                          |
| TROT<br><i>Timer Reload On Trigger</i> | 1 | then the counter is loaded on each trigger                                                                                                                                                                                            |
|                                        | 0 | then the counter is loaded on every T_EN rising edge or timeout rising edge (timeout not used in Capture modes)                                                                                                                       |
| TSOT<br><i>Timer Start On Trigger</i>  | 1 | then the counter will start to decrement on a trigger. Subsequent triggers are ignored until the counter times out.                                                                                                                   |
|                                        | 0 | then the counter decrements immediately on the next clock edge. When channel is Chained or in Capture mode, TSOT has no effect.                                                                                                       |

In different timer modes, these programmable bits affect the timer operation differently:

**Table 48-7. Time modes and programmable bits**

| Mode                         | Which programmable bits affect timer operations                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 32-bit Periodic Counter      | All bits (TSOT, TSOI, TROT) affect the timer operation as described previously.                                                                                      |
| Dual 16-bit Periodic Counter |                                                                                                                                                                      |
| 32-bit Trigger Accumulator   | <ul style="list-style-type: none"> <li>• Only the TSOI bit controls the timer function.</li> <li>• TROT and TSOT bits have no effect on timer operations.</li> </ul> |
| 32-bit Input Trigger Capture | <ul style="list-style-type: none"> <li>• Only TSOI and TROT bits control the timer function.</li> <li>• TSOT bit has no effect on timer operations.</li> </ul>       |

### 48.5.5 Channel Chaining

Individual timer channels can be chained together to achieve a larger value of timeout. Chaining the timer channel causes them to work in a '*nested loop*' manner thereby leading to an effective timeout value of  $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$ .

The channels are chained by setting the CHAIN bit in corresponding channel's  $TCTRL_{CHn}$  register. When a channel is chained, that channel's timer decrements on previous channel's timeout pulse, regardless of the timer mode (MODE bits). The TSOT bit does not have any effect if the channel timer (Channel 'n') is chained to previous channel's timer (Channel 'n-1').

### 48.5.6 Detailed timing

#### NOTE

The timing diagrams in these sections are not *cycle-accurate* (i.e., some cycles may not be shown), but the timing diagrams do show the timer channel behavior across several clock cycles.

**Table 48-8. Timing diagrams list**

| Mode                                         |    | Timing Diagram               | TSOT | TROT | TSOI | CHAIN |
|----------------------------------------------|----|------------------------------|------|------|------|-------|

### 48.5.6.1 Mode=00: 32-bit periodic counter (compare mode)

**Figure 48-5. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0**

**Figure 48-6. Case 2: TSOT = 0, TROT = 0, TSOI = 1, CHAIN = 0**

Figure 48-7. Case 3: TSOT = 0, TROT = 1, TSOI = 0, CHAIN = 0

Figure 48-8. Case 4: TSOT = 0, TROT = 1, TSOI = 1, CHAIN = 0

**Figure 48-9. Case 5: TSOT = 1, TROT = 0, TSOI = 0, CHAIN = 0**

**Figure 48-10. Case 6: TSOT = 1, TROT = 0, TSOI = 1, CHAIN = 0**

Mode=00  
32-bit Periodic Counter  
(Compare Mode)

Case 7: TSOT=1, TROT=1, TSOI=0, CHAIN=0

- Repeated interrupts with reload timer mode
- Output triggers will have unequal periods

Figure 48-11. Case 7: TSOT = 1, TROT = 1, TSOI = 0, CHAIN = 0

Mode=00  
32-bit  
Periodic Counter  
(Compare Mode)

Case 8: TSOT=1, TROT=1, TSOI=1, CHAIN=0

- Case shown for a non-periodic input trigger (might not be a usecase)
- If input trigger is periodic and greater than timer timeout then this will be the same as TROT=0
- If input trigger is periodic and less than timer timeout, then timer will never time out, and will always reload on input trigger (not a valid usecase)

Figure 48-12. Case 8: TSOT = 1, TROT = 1, TSOI = 1, CHAIN = 0

## 48.5.6.2 Mode=01: 16-bit dual periodic counter (compare mode)

**Figure 48-13. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0**

### Effect of Timer Control Bits in Mode=01:

- Effect of timer control bits are the same as for Mode=00. Refer to the individual figures of Mode=00.
- The Timer Interrupt (timeout) asserts when {TMR\_H,TMR\_L} = 0x0000\_0000.
- Behavior for Mode = 01 is explained in the next table.

**Table 48-9. Mode=01 timer control bits**

| TSOT | TROT | TSOI | Function                                                                                                                                     | Effect on Timer                                                                                                                                                                                                                    |

### 48.5.6.3 Mode=10: 32-bit trigger accumulator mode

Figure 48-14. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0

Mode=10  
32-bit Trigger  
Accumulator Mode

Case 2: TSOI=1, CHAIN=0 (TSOT,TROT=X)

- Useful for a ones-hot pulse counting mode
- Trigger and timeout generated after programmed number of pulses have been accumulated

Figure 48-15. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0

## 48.5.6.4 Mode=11: 32-bit trigger capture mode

Mode=11  
32-bit Trigger  
Capture Mode

Case 1: TSOI=0, TROT=0, CHAIN=0 (TSOT=X)

- Useful for determining duration between pulses
- Proper clock selection can ensure that the timer does not rollover more than once between 2 pulses

Figure 48-16. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0

Mode=11  
32-bit Trigger  
Capture Mode

### Case 2: TSOI=0, TROT=1, CHAIN=0 (TSOT=X)

- Useful for determining duration between pulses
- Selecting a fast timer clock provides accurate measurements but it can also cause timer rollover inbetween pulses

Figure 48-17. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0

Mode=11  
32-bit Trigger  
Capture Mode

## Case 3: TSOT=1, TROT=0, CHAIN=0 (TSOT=X)

- One-shot timer count mode
- Can be enabled again by making T\_EN=1

**Figure 48-18. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0**

## Case 4: TSOT = X, TROT = 1, TSOI = 1, CHAIN = 0

Same as previous case (Case 3), except that the timer reloads to 0xFFFF\_FFFF and then stops. The timer does not start until T\_EN is made 1 again. Case 4 is not a very useful case, because Case 3 covers this.

### 48.5.6.5 Timer chaining

#### Effect of Chaining

- Chaining causes Timer “n” to decrement on every timeout pulse (trigger output pulse) from Timer “n – 1”, regardless of what mode is configured in Timer “n”
- Timers “n” and “n – 1” effectively form a larger width timer (64-bits)
- More than 2 timer channels (or all timer channels) can be chained
- It is preferred to have the same trigger source and timer controls configured for chained channels

Figure 48-19. Chaining Effects

# Chapter 49

## Low Power Timer (LPTMR)

### 49.1 Chip-specific LPTMR information

#### 49.1.1 Instantiation Information

S32K1xx contains one LPTMR module with either a 1 channel 16-bit time counter or a 1 channel 16-bit pulse counter.

#### NOTE

The read of the LPTimer registers is affected during EEERAM commands. For more information see note 'During execution of the SetRAM 0xFF' in [Chip-specific FTFC information](#).

##### 49.1.1.1 LPT/HSCMP0 pulse counting

LPTMR\_ALT0 input is the selectable source to count pulses resulting from HSCMP0 Output (LPT\_ALT0 = HSCMP0 Output) via TRGMUX.

#### NOTE

- Low leakage mode and Wait mode are not supported in this device. See [Module operation in available power modes](#) for details on available power modes.
- For LPTMR\_PSR[PCS] bit options refer to table: Peripheral module clocking in section [Module clocks](#).
- $f_{\text{LPTMR}}$  referred in the chapter refers to  $f_{\text{BUS}}$  parameter in the datasheet.

### 49.1.2 LPTMR pulse counter input options

The LPTMR\_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following table shows the chip-specific input assignments for this bitfield.

**Table 49-1. Pulse counter input options**

| LPTMR_CSR[TPS] | Pulse counter input number | Chip input     |
|----------------|----------------------------|----------------|
| 00             | 0                          | TRGMUX output  |
| 01             | 1                          | LPTMR_ALT1 pin |
| 10             | 2                          | LPTMR_ALT2 pin |
| 11             | 3                          | LPTMR_ALT3 pin |

### 49.1.3 S32K11X to S32K14X difference

See [Differences between S32K14x/S32K14xW, and S32K11x](#), for differences arising out of CPU and interrupt latency impacting timed events when comparing S32K14X and S32K11X variants.

## 49.2 Introduction

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

### 49.2.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

## 49.2.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

**Table 49-2. Modes of operation**

| Modes       | Description                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------|
| Run         | The LPTMR operates normally.                                                                                                 |
| Wait        | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Stop        | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Low-Leakage | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Debug       | The LPTMR operates normally in Pulse Counter mode, but the counter does not increment in Time Counter mode.                  |

## 49.3 LPTMR signal descriptions

**Table 49-3. LPTMR signal descriptions**

| Signal     | I/O | Description             |
|------------|-----|-------------------------|
| LPTMR_ALTx | I   | Pulse Counter Input pin |

### 49.3.1 Detailed signal descriptions

**Table 49-4. LPTMR interface—detailed signal descriptions**

| Signal             | I/O | Description                                                                                         |                                                                                                                                                                                                                                                 |
|--------------------|-----|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPTMR_ALT <i>n</i> | I   | Pulse Counter Input<br>The LPTMR can select one of the input pins to be used in Pulse Counter mode. |                                                                                                                                                                                                                                                 |
|                    |     | State meaning                                                                                       | Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment.<br><br>Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment. |
|                    |     | Timing                                                                                              | Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.                                                                                                                                               |

## 49.4 Memory map and register definition

### NOTE

The LPTMR registers are reset only on a POR or LVD event.  
See [LPTMR power and reset](#) for more details.

### 49.4.1 LPTMR register descriptions

#### 49.4.1.1 LPTMR memory map

LPTMR0 base address: 4004\_0000h

| Offset | Register                                                      | Width<br>(In bits) | Access | Reset value |
|--------|---------------------------------------------------------------|--------------------|--------|-------------|
| 0h     | <a href="#">Low Power Timer Control Status Register (CSR)</a> | 32                 | RW     | 0000_0000h  |
| 4h     | <a href="#">Low Power Timer Prescale Register (PSR)</a>       | 32                 | RW     | 0000_0000h  |
| 8h     | <a href="#">Low Power Timer Compare Register (CMR)</a>        | 32                 | RW     | 0000_0000h  |
| Ch     | <a href="#">Low Power Timer Counter Register (CNR)</a>        | 32                 | RW     | 0000_0000h  |

#### 49.4.1.2 Low Power Timer Control Status Register (CSR)

##### 49.4.1.2.1 Offset

| Register | Offset |
|----------|--------|
| CSR      | 0h     |

### 49.4.1.2.2 Diagram

### 49.4.1.2.3 Fields

| Field      | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9<br>—  | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 8<br>TDRE  | <p>Timer DMA Request Enable</p> <p>When TDRE is set, the LPTMR DMA Request is generated whenever TCF is also set and the TCF is cleared when the DMA Controller is done.</p> <p>0b - Timer DMA Request disabled.<br/>1b - Timer DMA Request enabled.</p>                                                                                                                                                                                                 |
| 7<br>TCF   | <p>Timer Compare Flag</p> <p>TCF is set when the LPTMR is enabled and the CNR equals the CMR and increments. TCF is cleared when the LPTMR is disabled or a logic 1 is written to it.</p> <p><b>NOTE:</b> Ensure to clear this field before enabling the Timer interrupt or DMA request.</p> <p>0b - The value of CNR is not equal to CMR and increments.<br/>1b - The value of CNR is equal to CMR and increments.</p>                                  |
| 6<br>TIE   | <p>Timer Interrupt Enable</p> <p>When TIE is set, the LPTMR Interrupt is generated whenever TCF is also set.</p> <p>0b - Timer interrupt disabled.<br/>1b - Timer interrupt enabled.</p>                                                                                                                                                                                                                                                                 |
| 5-4<br>TPS | <p>Timer Pin Select</p> <p>Configures the input source to be used in Pulse Counter mode. TPS must be altered only when the LPTMR is disabled. The input connections vary by device. See the chip configuration information about connections to these inputs.</p> <p>00b - Pulse counter input 0 is selected.<br/>01b - Pulse counter input 1 is selected.<br/>10b - Pulse counter input 2 is selected.<br/>11b - Pulse counter input 3 is selected.</p> |
| 3<br>TPP   | <p>Timer Pin Polarity</p> <p>Configures the polarity of the input source in Pulse Counter mode. TPP must be changed only when the LPTMR is disabled.</p> <p>0b - Pulse Counter input source is active-high, and the CNR increments on the rising-edge.</p>                                                                                                                                                                                               |

Table continues on the next page...

## Memory map and register definition

| Field    | Function                                                                                                                                                                                                                                                                               |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | 1b - Pulse Counter input source is active-low, and the CNR increments on the falling-edge.                                                                                                                                                                                             |
| 2<br>TFC | Timer Free-Running Counter<br>When clear, TFC configures the CNR to reset whenever TCF is set. When set, TFC configures the CNR to reset on overflow. TFC must be altered only when the LPTMR is disabled.<br>0b - CNR is reset whenever TCF is set.<br>1b - CNR is reset on overflow. |
| 1<br>TMS | Timer Mode Select<br>Configures the mode of the LPTMR. TMS must be altered only when the LPTMR is disabled.<br>0b - Time Counter mode.<br>1b - Pulse Counter mode.                                                                                                                     |
| 0<br>TEN | Timer Enable<br>When TEN is clear, it resets the LPTMR internal logic, including the CNR and TCF. When TEN is set, the LPTMR is enabled. While writing 1 to this field, CSR[5:1] must not be altered.<br>0b - LPTMR is disabled and internal logic is reset.<br>1b - LPTMR is enabled. |

### 49.4.1.3 Low Power Timer Prescale Register (PSR)

#### 49.4.1.3.1 Offset

| Register | Offset |
|----------|--------|
| PSR      | 4h     |

#### 49.4.1.3.2 Diagram

### 49.4.1.3.3 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 15-0<br>COUNTER | Counter Value<br>The CNR returns the current value of the LPTMR counter at the time this register was last written. |

## 49.5 Functional description

### 49.5.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

## 49.5.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

### NOTE

The clock source selected by PSR[PCS] may need to be configured to remain enabled in low-power modes, otherwise the LPTMR does not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

### NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency  $f_{\text{LPTMR}}$  defined in the device datasheet.

## 49.5.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

### NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

### 49.5.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR increments every  $2^2$  to  $2^{16}$  prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR takes an additional one or two prescaler clock cycles due to synchronization logic.

### 49.5.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment takes an additional one or two prescaler clock cycles due to synchronization logic.

### 49.5.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

| If                                                                                                                   | Then                                     |
|----------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| The selected input source remains deasserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising edges | The glitch filter output also deasserts. |
| The selected input source remains asserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising-edges   | The glitch filter output also asserts.   |

### NOTE

The input is only sampled on the rising clock edge.

The CNR increments each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every  $2^2$  to  $2^{16}$  prescaler clock edges. When first enabled, the glitch filter waits an additional one or two prescaler clock edges due to synchronization logic.

### 49.5.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

## 49.5.4 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

When the core is halted in Debug mode:

- If configured for Pulse Counter mode, the CNR continues incrementing.
- If configured for Time Counter mode, the CNR stops incrementing.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This synchronizes and registers the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

## **49.5.5 LPTMR compare**

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

### **NOTE**

When the LPTMR is enabled in Time Counter mode, the first increment will take an additional one or two clock cycles due to synchronization logic. This will result in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster prescaler clock or larger prescaler value will minimize this impact.

### 49.5.6 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

### 49.5.7 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

| When                                                      | Then                                                                                                    |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| The CMR is set to 0 with CSR[TFC] clear                   | The LPTMR hardware trigger asserts on the first compare and does not deassert.                          |
| The CMR is set to a nonzero value, or, if CSR[TFC] is set | The LPTMR hardware trigger asserts on each compare and deasserts on the following increment of the CNR. |

## Chapter 50

# Real Time Clock (RTC)

### 50.1 Chip-specific RTC information

#### 50.1.1 RTC instantiation

The wakeup pin is not available for RTC on this device, therefore the related register bitfields are not applicable (e.g. RTC\_CR[WPS], RTC\_CR[WPE], and RTC\_IER[WPON]). Also there is no integrated capacitor for this device, therefore no tunable capacitors (included in the crystal oscillator) can be configured by software.

#### NOTE

There is no internal 32.768 kHz crystal oscillator available on this device. All references to 32.768 kHz clock in this chapter refers to RTC\_CLK. See RTC clocking in [Table 27-9](#) for available clock sources.

#### NOTE

The read of the RTC registers is affected during EEERAM commands. For more information see note 'During execution of the SetRAM 0xFF' in [Chip-specific FTFC information](#).

#### 50.1.2 RTC interrupts

Interrupts from RTC are enabled at reset as described in RTC\_IER register. Interrupt may occur as soon as they are enabled in NVIC.

#### 50.1.3 Software recommendation

Software reset should be provided to RTC before enabling it.

## 50.1.4 Multiple trigger

RTC is not able to generate multiple triggers in STOP and VLPS (via TRIGMUX). For instance, triggering LPIT in accumulator mode will not work due multiple trigger requirements. For other power modes, multiple triggers can be generated normally.

## 50.1.5 S32K11X to S32K14X difference

See [Differences between S32K14x/S32K14xW, and S32K11x](#), for differences arising out of CPU and interrupt latency impacting timed events when comparing S32K14X and S32K11X variants.

# 50.2 Introduction

## 50.2.1 Features

The RTC module features include:

- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Option to increment prescaler using a 1 kHz LPO (prescaler increments by 32 every clock edge)
- Register write protection
  - Lock register requires POR or software reset to enable write access
- Configurable 1, 2, 4, 8, 16, 32, 64 or 128 Hz square wave output with optional interrupt

## 50.2.2 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode.

### 50.2.3 RTC signal descriptions

Table 50-1. RTC signal descriptions

| Signal     | Description                                          | I/O |
|------------|------------------------------------------------------|-----|
| RTC_CLKOUT | Prescaler square-wave output or RTC 32.768 kHz clock | O   |

#### 50.2.3.1 RTC clock output

The RTC\_CLKOUT signal can output either a square wave prescaler output (configurable to 1, 2, 4, 8, 16, 32, 64 or 128 Hz) or the RTC 32.768 kHz clock.

## 50.3 Register definition

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

Write accesses to any register by non-supervisor mode software, when the supervisor access bit in the control register is clear, will terminate with a bus error.

Read accesses by non-supervisor mode software complete as normal.

Writing to a register protected by the lock register does not generate a bus error, but the write will not complete.

### 50.3.1 RTC register descriptions

#### 50.3.1.1 RTC memory map

RTC base address: 4003\_D000h

| Field       | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>TSR | Time Seconds Register<br><br>When the time counter is enabled, the TSR is read only and increments once a second provided SR[TOF] or SR[TIF] are not set. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TSR can be read or written. Writing to the TSR when the time counter is disabled will clear the SR[TOF] and/or the SR[TIF]. Writing to TSR with zero is supported, but not recommended because TSR will read as zero when SR[TIF] or SR[TOF] are set (indicating the time is invalid). |

### 50.3.1.3 RTC Time Prescaler Register (TPR)

#### 50.3.1.3.1 Offset

| Register | Offset |

| Field       | Function                                                                                                                                                                                                                                                                                                                                                           |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>—  | Reserved                                                                                                                                                                                                                                                                                                                                                           |
| 15-0<br>TPR | Time Prescaler Register<br>When the time counter is enabled, the TPR is read only and increments every 32.768 kHz clock cycle. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TPR can be read or written. The TSR[TSR] increments when bit 14 of the TPR transitions from a logic one to a logic zero. |

### 50.3.1.4 RTC Time Alarm Register (TAR)

#### 50.3.1.4.1 Offset

| Register | Offset |
|----------|--------|
| TAR      | 8h     |

### 50.3.1.4.2 Diagram

### 50.3.1.4.3 Fields

| Field | Function                                                                                                                                                           |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | Time Alarm Register                                                                                                                                                |
| TAR   | When the time counter is enabled, the SR[TAF] is set whenever the TAR[TAR] equals the TSR[TSR] and the TSR[TSR] increments. Writing to the TAR clears the SR[TAF]. |

## 50.3.1.5 RTC Time Compensation Register (TCR)

### 50.3.1.5.1 Offset

| Register | Offset |

| 7<br>LPOS | LPO Select<br>When set, the RTC prescaler increments using the LPO 1 kHz clock and not the RTC 32.768 kHz clock. The LPO increments the prescaler from bit TPR[5] (TPR[4:0] are ignored), supporting close to 1 second increment of the seconds register. Although compensation is supported when clocked from the LPO, TCR[4:0] of the compensation register are also ignored and only TCR[7:5] set the compensation value (can overflow after 1020 to 1027 cycles).<br>0b - RTC prescaler increments using 32.768 kHz clock.<br>1b - RTC prescaler increments using 1 kHz LPO, bits [4:0] of the prescaler are ignored. |

## 50.4 Functional description

### 50.4.1 Power, clocking, and reset

The RTC is an always powered block that remains active in all low power modes.

The time counter within the RTC is clocked by default from a 32.768 kHz clock. Alternatively, the time counter can be clocked by a LPO 1 kHz clock and the prescaler will increment by 32 for each LPO clock.

The power-on-reset signal initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers.

#### 50.4.1.1 Oscillator control

The 32.768 kHz crystal oscillator is disabled at POR and must be enabled by software. After enabling the crystal oscillator, wait the oscillator startup time before setting SR[TCE] or using the oscillator clock external to the RTC.

The crystal oscillator includes tunable capacitors that can be configured by software. Do not change the capacitance unless the oscillator is disabled.

#### 50.4.1.2 Software reset

Writing 1 to CR[SWR] forces the equivalent of a POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software.

### 50.4.1.3 Supervisor access

When the supervisor access control bit is clear, only supervisor mode software can write to the RTC registers, non-supervisor mode software will generate a bus error. Both supervisor and non-supervisor mode software can always read the RTC registers.

### 50.4.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle. There is also the option to clock the prescaler using a 1 kHz LPO that increments the prescaler by 32 on every clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz (or 1 kHz) clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows then the SR[TOF] will set and the time prescaler register will stop incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on POR and software reset and is cleared by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

### 50.4.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register will not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

When the prescaler is configured to increment using the 1 kHz LPO, the effective compensation value is divided by 32 and can only adjust the number of clock cycles between -4 and +3.

### 50.4.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] will set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This will usually be the next alarm value, although writing a value that is less than TSR, such as 0, will prevent SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

### 50.4.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

### 50.4.6 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next POR or software reset. Locking the Control register (CR) will disable the software reset. Locking LR will block future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

### 50.4.7 Interrupt

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on POR, and software reset. The RTC interrupt is enabled at the chip level by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode.

The RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The frequency of the seconds interrupt defaults to 1 Hz, but can instead be configured to trigger every 2, 4, 8, 16, 32, 64 or 128 Hz.

# Chapter 51

## Low Power Serial Peripheral Interface (LPSPI)

### 51.1 Chip-specific LPSPI information

#### 51.1.1 Instantiation Information

The following table summarizes the implementation of this module for each chip in the product series.

**Table 51-1. LPSPI configuration**

| Chip     | Instances | TX FIFO (word) | RX FIFO (word) | Chip selects |
|----------|-----------|----------------|----------------|--------------|
| S32K116  | LPSPi0    | 4              | 4              | 1            |
| S32K118  | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
| S32K142  | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
| S32K144  | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
|          | LPSPi2    | 4              | 4              |              |
| S32K144W | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
|          | LPSPi2    | 4              | 4              |              |
| S32K146  | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
|          | LPSPi2    | 4              | 4              |              |
| S32K148  | LPSPi0    | 4              | 4              |              |
|          | LPSPi1    | 4              | 4              |              |
|          | LPSPi2    | 4              | 4              |              |

1. The chip selects of LPSPI are package specific per S32K1xx variant. See tab 'PeripheralSummaries' of 'IO Signal Description Input Multiplexing' sheet attached to the Reference Manual for information on available chip selects.

The exact number of chip selects for each module depends on the package; not all chip selects are available on different packages. LPSPI2 does not support any TRGMUX-related feature, such as HREQ source from TRGMUX or any trigger to TRGMUX.

All documented LPSPI registers are present for all LPSPI instances on the device.

Low leakage and Wait modes are not supported in this device. See [Module operation in available power modes](#) for details on available power modes.

### NOTE

Quad-data mode is not supported in S32K11x series of devices.

## 51.2 Introduction

The LPSPI is a low power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus, either as a master and/or as a slave.

- The LPSPI is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPSPI can continue operating in stop modes, if an appropriate clock is available.
- The LPSPI supports DMA accesses and generates a DMA request.

The Serial Peripheral Interface bus (SPI) is a synchronous serial communication interface used in embedded systems, typically to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

- SPI devices communicate in full duplex mode using a master-slave scheme with a single master. This enables communication in both directions to happen simultaneously.
- Multiple slave devices are selected using individual slave select (SS) lines.
- The master device originates the frame for reading and writing.
- SPI accesses are always synchronous to the external clock.
- Each SPI can only assert one chip select at a time, but technically there can be multiple SPI slaves sharing the same chip select (in the form of a larger shift register). This requires:
  - the SDO of the master to connect to the SDI of the first slave,
  - the SDO of first slave to connect to the SDI of the next slave,
  - and the SDO of last slave to connect to the SDI of the LPSPI master.

Note that some SPI modules use MISO/MOSI for the input/output data.

## 51.2.1 Features

The LPSPI supports:

- Word size = 32 bits
- Configurable clock polarity and clock phase
- Master operation supporting up to 4 peripheral chip selects
- Slave operation
- Command/transmit FIFO of 4 words
- Receive FIFO of 4 words
- Flexible timing parameters in master mode, including SCK frequency and delays between PCS and SCK edges
- Support for full duplex transfers supporting 1-bit transmit and receive on each clock edge
- Support for half duplex transfers supporting 1-bit transmit or receive on each clock edge
- Support for half duplex transfers supporting 2-bit transmit or receive on each clock edge (master only)
- Support for half duplex transfers supporting 4-bit transmit or receive on each clock edge (master only)
- Host request can be used to control the start of a SPI bus transfer (master only)
- Receive data match logic supporting wakeup on data match

## 51.2.2 Block Diagram

Figure 51-1. Block Diagram

## 51.2.3 Modes of operation

Table 51-2. Chip modes supported by the LPSPI module

| Chip mode                                | LPSPI Operation                                                                                                                                                                      |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Run                                      | Normal operation                                                                                                                                                                     |
| Stop                                     | Can continue operating in stop mode if the Doze Enable bit (CR[DOZEN]) is clear and the LPSPI is using an external or internal clock source that remains operating during stop mode. |
| Debug (the core is in Debug/Halted mode) | Can continue operating in debug mode, if the Debug Enable bit (CR[DBGEN]) is set.                                                                                                    |

## 51.2.4 Signal Descriptions

**Table 51-3. Signals**

| Signal           | Name                                                                | Description                                                                                                                                                                                                                        | I/O |
|------------------|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| SCK              | Serial clock                                                        | <ul style="list-style-type: none"> <li>Input in slave mode</li> <li>Output in master mode</li> </ul>                                                                                                                               | I/O |
| PCS[0]           | Peripheral Chip Select                                              | <ul style="list-style-type: none"> <li>Input in slave mode</li> <li>Output in master mode</li> </ul>                                                                                                                               | I/O |
| PCS[1] / HREQ    | Peripheral Chip Select<br>or<br>Host Request                        | Host Request pin is selected when HREN=1 and HRSEL=0 <ul style="list-style-type: none"> <li>Input in either slave mode or when used as master Host Request</li> <li>Output in either master mode</li> </ul>                        | I/O |

## 51.3 Memory Map and Registers

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 51.3.1 LPSPI register descriptions

| Field | Function                                                    |
|-------|-------------------------------------------------------------|
| TDDE  | 0b - DMA request is disabled<br>1b - DMA request is enabled |

### 51.3.1.8 Configuration Register 0 (CFGR0)

#### 51.3.1.8.1 Offset

| Register | Offset |
|----------|--------|
| CFGR0    | 20h    |

#### 51.3.1.8.2 Function

The CFGR0 register includes additional fields to configure the LPSPI including Circular FIFO Enable and Receive Data Match Only.

### 51.3.1.10 Data Match Register 0 (DMR0)

#### 51.3.1.10.1 Offset

| Register | Offset |
|----------|--------|
| DMR0     | 30h    |

#### 51.3.1.10.2 Function

For the Data Match register to be available, set CFGR0[RDMO] = 1.

#### 51.3.1.10.3 Diagram

|       |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bits  | 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R     | MATCH0 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bits  | 15     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| R     | MATCH0 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

#### 51.3.1.10.4 Fields

| Field | Function      |
|-------|---------------|
| 31-0  | Match 0 Value |

| Field  | Function                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------------------------|
| MATCH0 | When Receive Data Match Only (CFGR0[RDMO]) is enabled, the Match 0 Value is compared against the received data. |

### 51.3.1.11 Data Match Register 1 (DMR1)

#### 51.3.1.11.1 Offset

| Register | Offset |
|----------|--------|
| DMR1     | 34h    |

#### 51.3.1.11.2 Function

The DMR1 register use depends on setting CFGR0[RDMO] = 1.

#### 51.3.1.11.3 Diagram

#### 51.3.1.11.4 Fields

| Field  | Function                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------------------------|
| 31-0   | Match 1 Value                                                                                                   |
| MATCH1 | When Receive Data Match Only (CFGR0[RDMO]) is enabled, the Match 1 Value is compared against the received data. |

## 51.3.1.12 Clock Configuration Register (CCR)

### 51.3.1.12.1 Offset

| Register | Offset |
|----------|--------|
| CCR      | 40h    |

### 51.3.1.12.2 Function

The Clock Configuration Register is only used in master mode, and the Clock Configuration Register cannot be changed when the LPSPI is enabled.

## 51.3.1.14 FIFO Status Register (FSR)

### 51.3.1.14.1 Offset

| Register | Offset |
|----------|--------|
| FSR      | 5Ch    |

### 51.3.1.14.2 Function

The FIFO Status register contains the TXCOUNT and RXCOUNT fields, which hold the number of words currently stored in the FIFO.

| 7-3<br>—         | Reserved                                                                                  |
| 2-0<br>TXCOUNT   | Transmit FIFO Count<br>Returns the number of words currently stored in the transmit FIFO. |

### 51.3.1.15 Transmit Command Register (TCR)

### 51.3.1.15.1 Offset

| Register | Offset |
|----------|--------|
| TCR      | 60h    |

### 51.3.1.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. The Command Register should only be written using 32-bit writes. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode**, writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI\_PCS negates.
- **In master mode**, if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode**, the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits.</li> </ul> |

### 51.3.1.16 Transmit Data Register (TDR)

#### 51.3.1.16.1 Offset

| Register | Offset |
|----------|--------|
| TDR      | 64h    |

#### 51.3.1.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written. The Data Register can be written using 32-bit, 16-bit or 8-bit writes, but each write will push data into the FIFO with zero pushed in unwritten bytes.

#### 51.3.1.16.3 Diagram

#### 51.3.1.16.4 Fields

| Field | Function      |
|-------|---------------|
| 31-0  | Transmit Data |

| Field | Function                                                                                                                                                                                                                                                                                         |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA  | Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes. |

### 51.3.1.17 Receive Status Register (RSR)

#### 51.3.1.17.1 Offset

| Register | Offset |
|----------|--------|
| RSR      | 70h    |

#### 51.3.1.17.2 Function

The Receive Status register contains data flow status fields for FIFO receive.

### 51.4.2 Master Mode

#### 51.4.2.1 Transmit and Command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- Transmit data words are stored to the transmit/command FIFO, by writing the Transmit Data Register (TDR).
- Command words are stored to the transmit/command FIFO, by writing the Transmit Command Register (TCR).

When a command word is at the top of the transmit/command FIFO, the actions that can occur depend upon whether the LPSPI module is either busy or between frames, the Continuous Transfer bit (TCR[CONT]), and the Continuing Command bit (TCR[CONTC]).

**Table 51-6. Possible actions when a command word is at the top of the transmit/command FIFO**

| Condition                                                                                                                                                | Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If the LPSPI is between frames                                                                                                                           | then the command word is pulled from the FIFO, and that command word controls all subsequent transfers.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| If LPSPI is busy and the Continuous Transfer bit (TCR[CONT]) is set or cleared and the Continuing Command bit (TCR[CONTC]) is cleared                    | then the SPI frame will complete at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with CONTC=0 will always terminate (stop) the existing transfer regardless of the previous CONT value.                                                                                                                                                      |
| If the LPSPI is busy and the existing Continuous Transfer bit (TCR[CONT]) is set or cleared and the new Continuing Command bit (TCR[CONTC]) value is set | then the command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last LPSPI_SCK pulse of the existing frame (based on the FRAMESZ configuration), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When the Continuing Command bit (TCR[CONTC]) is set, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. |

## NOTE

About the Continuous Transfer bit (CONT) and Continuing Command bit (CONTC):

- Continuous Transfer bit (CONT)=1 is used to keep PCS asserted at end of frame, allowing the transfer to continue.
- Continuing Command bit (CONTC)=1 is used to indicate that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

The Continuing Command bit (CONTC)=1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary, is when the previous command has the Continuous Transfer bit (CONT)=1.

The current state of the existing command word can be read by reading the Transmit Command Register (TCR). It requires at least 3 LPSPI functional clock cycles for the transmit command register to update after the transmit command register is written (assuming an empty FIFO) and the LPSPI must be enabled (Module Enable CR[MEN] bit is set).

Writing the transmit command register does not initiate a SPI bus transfer, unless the Transmit Data Mask (TCR[TXMSK]) bit is set. When the Transmit Data Mask bit is set, a new command word will not be loaded until the end of the existing frame (based on FRAMESZ configuration); at the end of the transfer, the TXMSK bit will be cleared.

In master mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers).

**Table 51-7. LPSPI Command Word in Master Mode**

| Transmit Command Register (TCR) |                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                            | Can this bit/field be modified during a data transfer? |
|---------------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Bit/Field                       | Name                   |                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                        |
| CPOL                            | Clock Polarity         | Configures the polarity of the LPSPI_SCK pin. Any change of CPOL value will cause a transition on the LPSPI_SCK pin.                                                                                                                                                                                                                                                                                                                   | N                                                      |
| CPHA                            | Clock Phase            | Configures the clock phase of the transfer.                                                                                                                                                                                                                                                                                                                                                                                            | N                                                      |
| PRESCALE                        | Prescaler Value        | Configures a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.                                                                                                                                                                        | N                                                      |
| PCS                             | Peripheral Chip Select | Configures which LPSPI_PCS asserts for the transfer; the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.                                                                                                                                                                                                                                                             | N                                                      |
| LSBF                            | LSB First              | Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.                                                                                                                                                                                                                                                                                                                                          | Y                                                      |
| BYSW                            | Byte Swap              | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.                                                                                                                                                                                                                                                                  | Y                                                      |
| CONT                            | Continuous Transfer    | Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at the frame size boundaries.                                                                                                                                                                                                   | Y                                                      |
| CONTC                           | Continuing Command     | Indicates that this is a new command word for the existing continuous transfer. The CONTC bit when set must only be written to the transmit/command FIFO on a frame boundary.                                                                                                                                                                                                                                                          | Y                                                      |
| RXMSK                           | Receive Data Mask      | Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.                                                                                                                                                                                                       | Y                                                      |
| TXMSK                           | Transmit Data Mask     | Masks the transmit data, so that masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFG1[OUTCFG]). Useful for half-duplex transfers.                                                                                                                                                                                                                      | Y                                                      |
| WIDTH                           | Transfer Width         | Configures the number of bits shifted on each LPSPI_SCK pulse. <ul style="list-style-type: none"> <li>1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</li> <li>2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one bit (Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be set.</li> </ul> | Y                                                      |

*Table continues on the next page...*

**Table 51-7. LPSPI Command Word in Master Mode (continued)**

| Transmit Command Register (TCR) |            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Can this bit/field be modified during a data transfer? |
|---------------------------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Bit/Field                       | Name       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                        |
| FRAMESZ                         | Frame Size | Configures the frame size in number of bits equal to (FRAMESZ + 1). <ul style="list-style-type: none"> <li>• The minimum frame size is 8 bits.</li> <li>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</li> <li>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</li> <li>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</li> </ul> | Y                                                      |

**SPI bus transfers:**

- The LPSPI initiates a SPI bus transfer when:
  - data is written to the transmit FIFO
  - and the HREQ pin is asserted (or disabled)
  - and the LPSPI is enabled
- To perform the SPI bus transfer, LPSPI uses the attributes configured in the Transmit Command Register (TCR) and uses the timing parameters in the Clock Configuration Register (CCR).
- The SPI bus transfer ends after the FRAMESZ configuration is reached, or at the end of a word when a new transmit command word is at the top of the transmit/command FIFO.
- The HREQ input is only checked on the next time that the LPSPI goes idle (the LPSPI completes the current transfer and the Transmit Command Register (TCR) is empty).

**Circular FIFO:** The transmit/command FIFO also supports a Circular FIFO feature, which enables the LPSPI master to (periodically) repeat a short data transfer that can fit within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled, the current state of the FIFO read pointer is saved and the status flags do not update. After the transmit/command FIFO is considered empty and the LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

### 51.4.2.2 Receive FIFO and Data Match

The receive FIFO is used to store receive data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] bit is set, the receive data is discarded instead of being stored in the receive FIFO.

- The receive data is written to the receive FIFO at the end of the frame.
- During a multiple word or continuous transfer, the receive data is also written to the receive FIFO at the same time as the new transmit data is read from the transmit FIFO.
- During a continuous transfer, if the transmit FIFO is empty, then the receive data is only written to the receive FIFO after the transmit FIFO is written or after the Transmit Command Register (TCR) is written to end the frame.

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The receive data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the Receive Data Mask TCR[RXMSK] bit cannot cause the data match to set, and will delay the receive data match on the first received data word, until all discarded data is received.
- The receiver data match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

### 51.4.2.3 Timing Parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the Clock Configuration Register (CCR) cannot be changed when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, the Prescaler Value TCR[PRESCALE] configuration can be changed between SPI bus transfers using the Transmit Command Register (TCR).

#### NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the datasheet specs based on the LPSPI functional clock frequency and prescaler value.

**Table 51-8. LPSPI Timing Parameters**

| Clock Configuration Register (CCR) |                         | Description                                                                                                                                                                                                                                                              | Min          | Max              |
|------------------------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|------------------|
| Bit/Field                          | Name                    |                                                                                                                                                                                                                                                                          |              |                  |
| SCKDIV                             | SCK Divider             | Configures the LPSPI_SCK clock period to (SCKDIV + 2) cycles. When SCK Divider is configured to an odd number of cycles, the first half of the LPSPI_SCK cycle is one cycle longer than the second half of the LPSPI_SCK cycle.                                          | 0 (2 cycles) | 255 (257 cycles) |
| DBT                                | Delay Between Transfers | Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT/2)+1 cycles between the command word update and any change on LPSPI_PCS pins.           | 0 (2 cycles) | 255 (257 cycles) |
| DBT                                | Delay Between Transfers | Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer. | 0 (1 cycle)  | 255 (256 cycles) |
| PCSSCK                             | PCS-to-SCK Delay        | Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.                                                                                                                                                                        | 0 (1 cycle)  | 255 (256 cycles) |
| SCKPCS                             | SCK-to-PCS Delay        | Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles.                                                                                                                                                                     | 0 (1 cycle)  | 255 (256 cycles) |

#### 51.4.2.4 Pin Configuration

- To swap directions or support half-duplex transfers on the same pin, the LPSPI\_SIN and LPSPI\_SOUT pins can be configured using the Pin Configuration CFGR1[PINCFG].
- To determine if an output data pin (like LPSPI\_SOUT) will tristate when the LPSPI\_PCS is negated, or if the output data pin will simply retain the last value, use the Output Config CFGR1[OUTCFG].
- When configuring for half-duplex transfers the output data pins must be configured to tristate when LPSPI\_PCS is negated; use the Output Config CFGR1[OUTCFG].
- When performing half-duplex 2-bit transfers, the Peripheral Chip Select Configuration CFGR1[PCSCFG] can be set to any value.
- When performing half-duplex 4-bit transfers, the Peripheral Chip Select Configuration CFGR1[PCSCFG] must equal 0x1.

### 51.4.2.5 Clock Loopback

The LPSPI master can be configured to use 1 of 2 clocks to sample the input data (for example, LPSPI\_SIN):

- either the LPSPI\_SCK output clock directly
- or a delayed version of the LPSPI\_SCK output clock

The delayed version of the LPSPI\_SCK is delayed by the LPSPI\_SCK pin output delay, plus the LPSPI\_SCK pin input delay, and is configured by setting CFGR1[SAMPLE]. Enabling the loopback version of the LPSPI\_SCK can improve the setup time of the input data from the slave.

**Figure 51-2. Clock Loopback**

See the device datasheet for the specific input setup time in master loopback mode.

### 51.4.3 Slave Mode

LPSPI slave mode:

- uses the same shift register and logic that master mode uses
- does not use the Clock Configuration Register (CCR)
- during SPI bus transfers, requires that the Transmit Command Register (TCR) remain static (unchanging)

### 51.4.3.1 Transmit and Command FIFO commands

Before enabling the LPSPI in slave mode, the Transmit Command Register (TCR) should be initialized, although the Transmit Command Register register will not update until after the LPSPI is enabled. After being enabled, the Transmit Command Register should only be changed if the LPSPI is idle. In slave mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers). Before the LPSPI\_PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag will set.

**Table 51-9. LPSPI Command Word in Slave Mode**

| Transmit Command Register (TCR) |                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit/Field                       | Name                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| CPOL                            | Clock Polarity         | Configures the polarity of the external LPSPI_SCK input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CPHA                            | Clock Phase            | Configures the clock phase of transfer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRESCALE                        | Prescaler Value        | Configures the LPSPI functional clock prescaler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PCS                             | Peripheral Chip Select | Configures which LPSPI_PCS is used, the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LSBF                            | LSB First              | Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| BYSW                            | Byte Swap              | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CONT                            | Continuous Transfer    | When Continuous Transfer is set in slave mode and after the first FRAMESZ bits are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CONTC                           | Continuing Command     | CONTC bit is reserved (in slave mode).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| RXMSK                           | Receive Data Mask      | Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TXMSK                           | Transmit Data Mask     | Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFGR1[OUTCFG]). Useful for half-duplex transfers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| WIDTH                           | Transfer Width         | Configures the number of bits shifted on each LPSPI_SCK pulse. <ul style="list-style-type: none"> <li>1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FRAMESZ                         | Frame Size             | Configures the frame size in number of bits equal to (FRAMESZ + 1). <ul style="list-style-type: none"> <li>The minimum frame size is 8 bits.</li> <li>The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</li> <li>If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</li> <li>If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</li> </ul> |

### 51.4.3.2 Receive FIFO and Data Match

The receive FIFO is used to store received data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] is set, the received data is discarded (instead of storing the received data in the receive FIFO).

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded (because the Receive Data Mask TCR[RXMSK] is set) cannot cause the data match to set, and will delay the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

### 51.4.3.3 Clocked Interface

The LPSPI module supports interfacing to external masters that provide only clock and data pins (LPSPI\_PCS is not required). This interface requires:

- using Clock Phase TCR[CPHA] = 1 (data is changed on the leading edge of SCK and captured on the following edge)
- configuring the LPSPI\_PCS input to be always asserted (configure the Peripheral Chip Select Polarity CFGR1[PCSPOL[n]] = 1). For example, to configure PCS[0] to be always asserted, set PCSPOL[0] = 1, and don't configure PCS[0] in the pin muxing.
- setting the Automatic PCS CFGR1[AUTOPCS] bit = 1 (Automatic PCS generation is enabled). When Automatic PCS generation (AUTOPCS) is set, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last LPSPI\_SCK edge of one word and the first LPSPI\_SCK edge of the next word.

### 51.4.4 Interrupts and DMA Requests

The next table lists the slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit/receive DMA requests.

**Table 51-10. LPSPI Interrupts and DMA Requests**

| Status Register (SR) |                        | Description                                                                                                                                                                                             | Can generate |              |                   |
|----------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------|-------------------|
| Status Flag          | Name                   |                                                                                                                                                                                                         | Interrupt?   | DMA Request? | Low Power Wakeup? |
| TDF                  | Transmit Data Flag     | Data can be written to transmit FIFO, as configured by the Transmit FIFO Watermark FCR[TXWATER]                                                                                                         | Y            | TX           | Y                 |
| RDF                  | Receive Data Flag      | Data can be read from the receive FIFO, as configured by the Receive FIFO Watermark FCR[RXWATER]                                                                                                        | Y            | RX           | Y                 |
| WCF                  | Word Complete Flag     | Word is complete, the last bit of the word has been sampled                                                                                                                                             | Y            | N            | Y                 |
| FCF                  | Frame Complete Flag    | Frame is complete, and PCS has negated                                                                                                                                                                  | Y            | N            | Y                 |
| TCF                  | Transfer Complete Flag | Transfer is complete, PCS has negated, and the transmit/command FIFO is empty                                                                                                                           | Y            | N            | Y                 |
| TEF                  | Transmit Error Flag    | Indicates a transmit/command FIFO underrun. In master mode when the No Stall CFGR1[NOSTALL] bit is clear (0, transfers will stall when transmit FIFO is empty), the Transmit Error Flag bit cannot set. | Y            | N            | Y                 |
| REF                  | Receive Error Flag     | Receive error flag, indicates a receive FIFO overflow.                                                                                                                                                  | Y            | N            | Y                 |
| DMF                  | Data Match Flag        | Indicates that the received data has matched the configured data match value                                                                                                                            | Y            | N            | Y                 |
| MBF                  | Module Busy Flag       | LPSPI is busy performing a SPI bus transfer                                                                                                                                                             | N            | N            | N                 |

### 51.4.5 Peripheral Triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

**Table 51-11. LPSPI Triggers**

| Trigger              | Description                                                                                                                                                                       |                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Frame Output Trigger | The frame output trigger: <ul style="list-style-type: none"><li>• asserts at the end of each frame (when PCS negates)</li><li>• remains asserted until PCS next asserts</li></ul> | The LPSPI generates 2 output triggers that can be connected to other peripherals on the device. |
| Word Output Trigger  | The word output trigger: <ul style="list-style-type: none"><li>• asserts at the end of each received word</li><li>• remains asserted for 1 LPSPI_SCK period</li></ul>             |                                                                                                 |
| Input Trigger        | To control the start of a LPSPI bus transfer, the LPSPI input trigger can be selected instead of the LPSPI_HREQ input.                                                            |                                                                                                 |

**Table 51-11. LPSPI Triggers**

| Trigger | Description                                                                                                                                                                                                                                                                                                                                                         |

|         | <ul style="list-style-type: none"><li>• The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected.</li><li>• When the LPSPI module is busy, the LPSPI_HREQ input (and therefore the LPSPI input trigger) is ignored .</li></ul> |

# Chapter 52

## Low Power Inter-Integrated Circuit (LPI2C)

### 52.1 Chip-specific LPI2C information

#### 52.1.1 Instantiation information

The following table summarizes the implementation of this module for each chip in the product series.

**Table 52-1. LPI2C configuration**

| Chip     | Instances | TX FIFO (word) | RX FIFO (word) | SMBus | Slave mode enable |
|----------|-----------|----------------|----------------|-------|-------------------|
| S32K116  | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K118  | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K142  | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K144  | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K144W | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K146  | LPI2C0    | 4              | 4              | Yes   | Yes               |
| S32K148  | LPI2C0    | 4              | 4              | Yes   | Yes               |
|          | LPI2C1    | 4              | 4              | Yes   | Yes               |

Low leakage and Wait mode is not supported in this device. See [Module operation in available power modes](#) for details on available power modes.

HS-Mode (baud-rates above 400 kbps) is not supported on this device.

The LPI2C module includes SMBus support and DMA support.

#### NOTE

- Only SIRC is the valid clock source in VLP modes. As the SIRC supports the LPI2C data rates, it is recommended to

use SIRC for LPI2C to avoid clock reconfiguration and switching times.

- HREQ is not supported for 32-pin QFN and 48-pin LQFP packages on any S32K1xx device.

## 52.2 Introduction

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I<sup>2</sup>C bus as a master and/or as a slave.

- The LPI2C implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- The LPI2C is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPI2C can continue operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 2. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

### NOTE

The I<sup>2</sup>C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

### 52.2.1 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.

- When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism for multiple laves.
- When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4words.
- Receive FIFO of 4words.
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

# 52.2.2 Block Diagram

Figure 52-1. LPI2C block diagram

# 52.2.3 Modes of operation

Table 52-2. Chip modes supported by the LPI2C module

| Chip mode | LPI2C Operation                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Run       | Normal operations                                                                                                                                                                     |
| Stop      | Can continue operating in stop mode if the Doze Enable bit (MCR[DOZEN]) is clear and the LPI2C is using an external or internal clock source that remains operating during stop mode. |
| Debug     | Can continue operating in debug mode if the Debug Enable bit (MCR[DBGE]) is set.                                                                                                      |

## 52.2.4 Signal Descriptions

**Table 52-3. Signals**

| Signal | Name                     | 2-Wire Scheme                                                                                        | 4-Wire Scheme                                                                                                                              | I/O |
|--------|--------------------------|------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|-----|
| SCL    | LPI2C clock line         | SCL                                                                                                  | In 4-wire mode, this is the SCL input pin.                                                                                                 | I/O |
| SDA    | LPI2C data line          | SDA                                                                                                  | In 4-wire mode, this is the SDA input pin.                                                                                                 | I/O |
| HREQ   | Host request             | If host request is asserted and the I2C bus is idle, then it will initiate an LPI2C master transfer. |                                                                                                                                            | I   |
| SCLS   | Secondary I2C clock line | Not used                                                                                             | In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SCL pin. | I/O |
| SDAS   | Secondary I2C data line  | Not used                                                                                             | In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SDA pin. | I/O |

## 52.3 Functional description

### 52.3.1 Clocking and Resets

For device-specific clocking information, refer to the Clocking chapter.

**Table 52-4. Clocks**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPI2C Functional clock | The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth.                                                                           |
| External clock         | <p>The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled.</p> <p><b>NOTE:</b> The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time.</p> |
| Bus clock              | The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers.                                                                                                                                                                                                                                                                                   |

**Table 52-5. Resets**

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chip reset     | The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset.                                                                                                                                                                                                                                                                                                                                 |
| Software reset | <ul style="list-style-type: none"> <li>• The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] will reset all master logic and registers to their default state, except for the MCR itself.</li> <li>• The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] will reset all slave logic and registers to their default state, except for the SCR itself.</li> </ul>     |
| FIFO reset     | <ul style="list-style-type: none"> <li>• The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty.</li> <li>• The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.</li> </ul> |

## 52.3.2 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

### 52.3.2.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP condition; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master will automatically transmit a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example, HS-mode master code) must be followed by a STOP or (repeated) START condition.

### 52.3.2.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master will initiate a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to  $(MCCR0[CLKLO] + 1)$  multiplied by the prescaler (MCFGR1[PRESALE]).
- Transmit a START condition and address byte using the timing configuration in the Master Clock Configuration Register 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration Register 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C will continue to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C will generate a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this will result in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

### 52.3.2.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and will delay the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

### 52.3.2.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (MCCR1) and other modes (MCCR0). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

**Table 52-6. Timing Parameters**

| I2C Specification Timing Parameter   | I2C Specification Timing Symbol | LPI2C Timing Parameter (LPI2C functional clock cycles)            |
|--------------------------------------|---------------------------------|-------------------------------------------------------------------|
| SCL clock period                     | tSCL                            | $(CLKHI + CLKLO + 2 + SCL\_LATENCY) \times (2^{\wedge} PRESCALE)$ |
| hold time (repeated) START condition | tHD:STA                         | $(SETHOLD + 1) \times (2^{\wedge} PRESCALE)$                      |
| LOW period of the SCL clock          | tLOW                            | $(CLKLO + 1) \times (2^{\wedge} PRESCALE)$                        |

**Table 52-6. Timing Parameters (continued)**

| I2C Specification Timing Parameter                          | I2C Specification Timing Symbol           | LPI2C Timing Parameter (LPI2C functional clock cycles)    |
|-------------------------------------------------------------|-------------------------------------------|-----------------------------------------------------------|
| HIGH period of the SCL clock                                | t <sub>HIGH</sub>                         | $(CLKHI + 1 + SCL\_LATENCY) \times (2 \wedge PRESCALE)$   |
| setup time for a repeated START condition or STOP condition | t <sub>SU:STA</sub> , t <sub>SU:STO</sub> | $(SETHOLD + 1 + SCL\_LATENCY) \times (2 \wedge PRESCALE)$ |
| data hold time                                              | t <sub>HD:DAT</sub>                       | $(DATAVD + 1) \times (2 \wedge PRESCALE)$                 |
| data setup time                                             | t <sub>SU:DAT</sub>                       | $(SDA\_LATENCY + 1) \times (2 \wedge PRESCALE)$           |
| bus free time between a STOP and START condition            | t <sub>BUF</sub>                          | $(CLKLO + 1 + SDA\_LATENCY) \times (2 \wedge PRESCALE)$   |
| data valid time, data valid acknowledge time                | t <sub>VD:DAT</sub> , t <sub>VD:ACK</sub> | $(DATAVD + 1) \times (2 \wedge PRESCALE)$                 |

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading and the external pull-up resistor sizing. A larger risetime will increase the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

**Table 52-7. Synchronization Latency**

| Timing Parameter | Timing Definition                                                   |
|------------------|---------------------------------------------------------------------|
| SCL_LATENCY      | $ROUNDDOWN ( (2 + FILTSCL + SCL\_RISETIME) / (2 \wedge PRESCALE) )$ |
| SDA_LATENCY      | $ROUNDDOWN ( (2 + FILTSDA + SDA\_RISETIME) / (2 \wedge PRESCALE) )$ |

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

**Table 52-8. LPI2C Timing Parameter Restrictions**

| Timing Parameter | Minimum | Maximum                                  | Comment                                                                             |
|------------------|---------|------------------------------------------|-------------------------------------------------------------------------------------|
| CLKLO            | 0x03    | -                                        | Also: $CLKLO \times (2 \wedge PRESCALE) > SCL\_LATENCY$                             |
| CLKHI            | 0x01    | -                                        | Configure CLKHI to meet the duty cycle requirements in the I2C specification        |
| SETHOLD          | 0x02    | -                                        | Also: $SETHOLD \times (2 \wedge PRESCALE) > SDA\_LATENCY$                           |
| DATAVD           | 0x01    | $CLKLO - SDA\_LATENCY - 1$               | Configure DATAVD to meet the data hold requirement in the I2C specification         |
| FILTSCL          | 0x00    | $[CLKLO \times (2 \wedge PRESCALE)] - 3$ | FILTSCL and FILTSDA are the only parameters not multiplied by $(2 \wedge PRESCALE)$ |

Table continues on the next page...

**Table 52-8. LPI2C Timing Parameter Restrictions (continued)**

| Timing Parameter | Minimum                                        | Maximum                                                  | Comment                                                                                               |
|------------------|------------------------------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| FILTSDA          | FILTSCSCL                                      | $[\text{CLKLO} \times (2^{\wedge} \text{PRESCALE})] - 3$ | Configuring FILTSDA greater than FILTSCSCL can delay the SDA input to compensate for board level skew |
| BUSIDLE          | $(\text{CLKLO} + \text{SETHOLD} + 2) \times 2$ | -                                                        | Must also be greater than $(\text{CLKHI} + 1)$                                                        |

The timing parameters must be configured to meet the requirements of the I2C specification; this will depend on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

**Table 52-9. LPI2C Example Timing Configurations**

| I2C Mode | Clock Frequency | Baud Rate | PRESCALE | FILTSCSCL / FILTSDA | SETHOLD | CLKLO | CLKHI | DATAVD |
|----------|-----------------|-----------|----------|---------------------|---------|-------|-------|--------|
| Fast     | 8 MHz           | 400 kbps  | 0x0      | 0x0/0x0             | 0x04    | 0x0B  | 0x05  | 0x02   |
| Fast+    | 8 MHz           | 1 Mbps    | 0x0      | 0x0/0x0             | 0x02    | 0x03  | 0x01  | 0x01   |
| Fast     | 48 MHz          | 400 kbps  | 0x0      | 0x1/0x1             | 0x1D    | 0x3E  | 0x35  | 0x0F   |
| Fast     | 48 MHz          | 400 kbps  | 0x2      | 0x1/0x1             | 0x07    | 0x11  | 0x0B  | 0x03   |
| Fast+    | 48 MHz          | 1 Mbps    | 0x2      | 0x1/0x1             | 0x03    | 0x06  | 0x04  | 0x04   |
| HS-mode  | 48 MHz          | 3.2 Mbps  | 0x0      | 0x0/0x0             | 0x07    | 0x08  | 0x03  | 0x01   |
| Fast     | 60 MHz          | 400 kbps  | 0x1      | 0x2/0x2             | 0x11    | 0x28  | 0x1F  | 0x08   |
| Fast+    | 60 MHz          | 1 Mbps    | 0x1      | 0x2/0x2             | 0x07    | 0x0F  | 0x0B  | 0x01   |
| HS-mode  | 60 MHz          | 3.33 Mbps | 0x1      | 0x0/0x0             | 0x04    | 0x04  | 0x02  | 0x01   |

### 52.3.2.5 Error Conditions

The LPI2C master will monitor for errors while it is active, the following conditions will generate an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).

- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] \* 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PTLF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[SWRST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

### 52.3.2.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the IGNACK bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This will configure the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the

LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

### 52.3.3 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

#### 52.3.3.1 Address Matching

The LPI2C slave can be configured:

- to match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- to match a range of addresses in either 7-bit or 10-bit addressing modes
- to match the General Call Address, and generate appropriate flags
- to match the SMBus Alert Address, and generate appropriate flags
- to detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave will automatically perform slave-transmit or slave-receive transfers until:

- a NACK is detected (unless IGNACK is set)
- a bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- a (repeated) START or STOP condition is detected

#### 52.3.3.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and RXCFG=1).
- The Address Status register should only be read when the Address Valid flag is set.

### 52.3.3.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching will extend for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

### 52.3.3.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

### 52.3.3.5 Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag will set when the I2C slave is driving SDA, but samples a different value than what is expected.
- FIFO error flag will set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag will also set due to an address overrun when RXCFG is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The I2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the I2C master logic should be used and so software can reset the I2C slave when this condition is detected.

### 52.3.4 Interrupts and DMA Requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The I2C master and slave interrupts may be combined
- The I2C master and slave transmit DMA requests may be combined
- The I2C master and slave receive DMA requests may be combined

#### 52.3.4.1 Master mode

The next table lists the master mode sources that can generate I2C master interrupts and I2C master transmit/receive DMA requests.

**Table 52-10. Master Interrupts and DMA Requests**

| Master Status Register (MSR) |                    | Description                                                                                                                | Can generate |              |                   |
|------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------|--------------|--------------|-------------------|
| Flag                         | Name               |                                                                                                                            | Interrupt?   | DMA Request? | Low Power Wakeup? |
| TDF                          | Transmit Data Flag | Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER]                           | Y            | TX           | Y                 |
| RDF                          | Receive Data Flag  | Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER]                          | Y            | RX           | Y                 |
| EPF                          | End Packet Flag    | Master has transmitted a Repeated START or STOP condition                                                                  | Y            | N            | Y                 |
| SDF                          | STOP Detect Flag   | Master has transmitted a STOP condition                                                                                    | Y            | N            | Y                 |
| NDF                          | NACK Detect Flag   | <ul style="list-style-type: none"> <li>• During an address byte, the master expected an ACK but detected a NACK</li> </ul> | Y            | N            | Y                 |

*Table continues on the next page...*

**Table 52-10. Master Interrupts and DMA Requests (continued)**

| Master Status Register (MSR) |                       | Description                                                                                                                                                                                                                                        | Can generate |              |                   |
|------------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------|-------------------|
| Flag                         | Name                  |                                                                                                                                                                                                                                                    | Interrupt?   | DMA Request? | Low Power Wakeup? |
|                              |                       | <ul style="list-style-type: none"> <li>During an address byte, the master expected a NACK but detected an ACK</li> <li>During a master-transmitter data byte, the master detected a NACK</li> </ul>                                                |              |              |                   |
| ALF                          | Arbitration Lost Flag | <ul style="list-style-type: none"> <li>The master lost arbitration due to a START/STOP condition detected at the wrong time</li> <li>Or the master was transmitting data but received different data than the data that was transmitted</li> </ul> | Y            | N            | Y                 |
| FEF                          | FIFO Error Flag       | The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition                                                                                                                     | Y            | N            | Y                 |
| PLTF                         | Pin Low Timeout Flag  | Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout                                                                                                                                            | Y            | N            | Y                 |
| DMF                          | Data Match Flag       | The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry                                                                                                                            | Y            | N            | Y                 |
| MBF                          | Master Busy Flag      | LPI2C master is busy transmitting/receiving data                                                                                                                                                                                                   | N            | N            | N                 |
| BBF                          | Bus Busy Flag         | LPI2C master is enabled and activity is detected on I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred.                                                                                      | N            | N            | N                 |

### 52.3.4.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

**Table 52-11. Slave Interrupts and DMA Requests**

| Slave Status Register (SSR) |                    | Description                                                       | Can generate |              |                   |
|-----------------------------|--------------------|-------------------------------------------------------------------|--------------|--------------|-------------------|
| Flag                        | Name               |                                                                   | Interrupt?   | DMA Request? | Low Power Wakeup? |
| TDF                         | Transmit Data Flag | Data can be written to the Slave Transmit Data Register (STDR)    | Y            | TX           | Y                 |
| RDF                         | Receive Data Flag  | Data can be read from the Slave Receive Data Register (SRDR)      | Y            | RX           | Y                 |
| AVF                         | Address Valid Flag | Address can be read from the Slave Address Status Register (SASR) | Y            | RX           | Y                 |

*Table continues on the next page...*

**Table 52-11. Slave Interrupts and DMA Requests (continued)**

| Slave Status Register (SSR) |                           | Description                                                                                                                                                                                                                                                        | Can generate |              |                   |
|-----------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------|-------------------|
| Flag                        | Name                      |                                                                                                                                                                                                                                                                    | Interrupt?   | DMA Request? | Low Power Wakeup? |
| TAF                         | Transmit ACK Flag         | ACK/NACK can be written to the Slave Transmit ACK Register (STAR)                                                                                                                                                                                                  | Y            | N            | Y                 |
| RSF                         | Repeated Start Flag       | Slave has detected an address match followed by a Repeated START condition                                                                                                                                                                                         | Y            | N            | Y                 |
| SDF                         | STOP Detect Flag          | Slave has detected an address match followed by a STOP condition                                                                                                                                                                                                   | Y            | N            | Y                 |
| BEF                         | Bit Error Flag            | Slave was transmitting data, but received different data than what was transmitted                                                                                                                                                                                 | Y            | N            | Y                 |
| FEF                         | FIFO Error Flag           | <ul style="list-style-type: none"> <li>• Transmit data underrun</li> <li>• Receive data overrun</li> <li>• Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1, )</li> </ul> <p>FEF flag can only set when clock stretching is disabled.</p> | Y            | N            | Y                 |
| AM0F                        | Address Match 0 Flag      | Slave detected an address match with SAMR[ADDR0] field                                                                                                                                                                                                             | Y            | N            | N                 |
| AM1F                        | Address Match 1 Flag      | Slave detected an address match with SAMR[ADDR1] field or using an address range                                                                                                                                                                                   | Y            | N            | N                 |
| GCF                         | General Call Flag         | Slave detected an address match with the General Call address                                                                                                                                                                                                      | Y            | N            | N                 |
| SARF                        | SMBus Alert Response Flag | Slave detected an address match with the SMBus Alert address                                                                                                                                                                                                       | Y            | N            | N                 |
| SBF                         | Slave Busy Flag           | LPI2C slave is busy receiving an address byte or is transmitting/receiving data                                                                                                                                                                                    | N            | N            | N                 |
| BBF                         | Bus Busy Flag             | LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected                                                                                                                                                    | N            | N            | N                 |

### 52.3.5 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

**Table 52-12. LPI2C Triggers**

| Trigger               | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master Output Trigger | The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.                                                                            |
| Slave Output Trigger  | The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.                                                                      |
| Input Trigger         | To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored. |

## 52.4 Memory Map and Registers

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 52.4.1 LPI2C register descriptions

#### 52.4.1.1 LPI2C memory map

LPI2C0 base address: 4006\_6000h

LPI2C1 base address: 4006\_7000h

## Memory Map and Registers

| Offset | Register                                      | Width<br>(In bits) | Access | Reset value |
|--------|-----------------------------------------------|--------------------|--------|-------------|
| 0h     | Version ID Register (VERID)                   | 32                 | RO     | 0100_0003h  |
| 4h     | Parameter Register (PARAM)                    | 32                 | RO     | 0000_0202h  |
| 10h    | Master Control Register (MCR)                 | 32                 | RW     | 0000_0000h  |
| 14h    | Master Status Register (MSR)                  | 32                 | W1C    | 0000_0001h  |
| 18h    | Master Interrupt Enable Register (MIER)       | 32                 | RW     | 0000_0000h  |
| 1Ch    | Master DMA Enable Register (MDER)             | 32                 | RW     | 0000_0000h  |
| 20h    | Master Configuration Register 0 (MCFGR0)      | 32                 | RW     | 0000_0000h  |
| 24h    | Master Configuration Register 1 (MCFGR1)      | 32                 | RW     | 0000_0000h  |
| 28h    | Master Configuration Register 2 (MCFGR2)      | 32                 | RW     | 0000_0000h  |
| 2Ch    | Master Configuration Register 3 (MCFGR3)      | 32                 | RW     | 0000_0000h  |
| 40h    | Master Data Match Register (MDMR)             | 32                 | RW     | 0000_0000h  |

## 52.4.1.2 Version ID Register (VERID)

### 52.4.1.2.1 Offset

| Register | Offset |
|----------|--------|
| VERID    | 0h     |

### 52.4.1.2.2 Function

Contains version numbers for the module design and feature set.

### 52.4.1.2.3 Diagram

### 52.4.1.2.4 Fields

| Field           | Function                                                                                                                                                                                                          |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>MAJOR  | Major Version Number<br>Returns the major version number for the module design specification. Read-only field.                                                                                                    |
| 23-16<br>MINOR  | Minor Version Number<br>Returns the minor version number for the module design specification. Read-only field.                                                                                                    |
| 15-0<br>FEATURE | Feature Specification Number<br>Returns the feature set number. Read-only field.<br>0000000000000010b - Master only, with standard feature set<br>0000000000000011b - Master and slave, with standard feature set |

## 52.4.1.3 Parameter Register (PARAM)

### 52.4.1.3.1 Offset

| Register | Offset |
|----------|--------|
| PARAM    | 4h     |

### 52.4.1.3.2 Function

Contains parameter values that were implemented in the module.

### 52.4.1.3.3 Diagram

### 52.4.1.3.4 Fields

| Field           | Function                                                                                                        |

|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RDMO         | When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to set is discarded. After the Data Match Flag is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing the Data Match Flag, to ensure that no receive data is lost.<br>0b - Received data is stored in the receive FIFO<br>1b - Received data is discarded unless the the Data Match Flag (MSR[DMF]) is set                                                                                                                                                   |
| 8<br>CIRFIFO | Circular FIFO Enable<br>When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO will be emptied as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This will cause the contents of the transmit FIFO to be cycled through repeatedly. If AUTOSTOP is set, then a STOP condition will be sent whenever the transmit FIFO is empty and the read pointer is restored.<br>0b - Circular FIFO is disabled<br>1b - Circular FIFO is enabled |

## 52.4.1.10 Master Configuration Register 2 (MCFGR2)

### 52.4.1.10.1 Offset

| Register | Offset |
|----------|--------|
| MCFGR2   | 28h    |

### 52.4.1.10.2 Function

The Master Configuration Register 2 should only be written when the I2C Master is disabled.

| 5-0<br>CLKLO     | Clock Low Period<br>Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to $(2 + \text{FILTSCl}) / 2^{\text{PRESCALE}}$ cycles.                                                                                                              |

### 52.4.1.14 Master Clock Configuration Register 1 (MCCR1)

#### 52.4.1.14.1 Offset

| Register | Offset |
|----------|--------|
| MCCR1    | 50h    |

### 52.4.1.14.2 Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by MCCR0), before switching to high speed mode (with timing configured by MCCR1).

| 7-6<br>—     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5-0<br>CLKLO | Clock Low Period<br>Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to $(2 + \text{FILTSCl}) / 2^{\text{PRESCALE}}$ cycles. |

### 52.4.1.15 Master FIFO Control Register (MFCR)

#### 52.4.1.15.1 Offset

| Register | Offset |
|----------|--------|
| MFCR     | 58h    |

#### 52.4.1.15.2 Function

The Master FIFO control register is only used in Stop mode when the MFCR register is static (i.e., the MFCR register is not changing).

#### 52.4.1.15.3 Diagram

#### 52.4.1.16.3 Fields

| Field | Function |
|-------|----------|
| 31-19 | Reserved |

Table continues on the next page...

## Memory Map and Registers

| Field            | Function                                                                 |
|------------------|--------------------------------------------------------------------------|
| —                |                                                                          |
| 18-16<br>RXCOUNT | Receive FIFO Count<br>Returns the number of words in the receive FIFO.   |
| 15-3<br>—        | Reserved                                                                 |
| 2-0<br>TXCOUNT   | Transmit FIFO Count<br>Returns the number of words in the transmit FIFO. |

### 52.4.1.17 Master Transmit Data Register (MTDR)

#### 52.4.1.17.1 Offset

| Register | Offset |
|----------|--------|
| MTDR     | 60h    |

#### 52.4.1.17.2 Function

- An 8-bit write to the CMD field will store the data in the Command FIFO, but does not increment the FIFO write pointer.
- An 8-bit write to the DATA field will zero extend the CMD field, unless the CMD field has been written separately since the last FIFO write; it (the 8-bit write) also increments the FIFO write pointer.
- A 16-bit or 32-bit will write both the CMD and DATA fields and increment the FIFO.

#### 52.4.1.17.3 Diagram

### 52.4.1.18.3 Fields

| Field         | Function                                                                                                                                                                                                                                     |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 52.4.1.23 Slave Configuration Register 1 (SCFGR1)

### 52.4.1.23.1 Offset

| Register | Offset |
|----------|--------|
| SCFGR1   | 124h   |

### 52.4.1.23.2 Function

The Slave Configuration Register 1 should only be written when the I2C Slave is disabled.

| ADRSTALL | Enables SCL clock stretching when the Address Valid Flag (SSR[AVF]) is asserted. Clock stretching only occurs following the 9th bit, and is therefore compatible with high speed mode.<br>0b - Clock stretching is disabled<br>1b - Clock stretching is enabled |

## 52.4.1.24 Slave Configuration Register 2 (SCFGR2)

### 52.4.1.24.1 Offset

| Register | Offset |
|----------|--------|
| SCFGR2   | 128h   |

### 52.4.1.24.2 Function

The Slave Configuration Register 2 should only be written when the I2C Slave is disabled.

| 10-0<br>RADDR | Received Address<br>The Received Address updates whenever the AMF is set; the AMF is cleared by reading the Slave Address Status register. <ul style="list-style-type: none"> <li>In 7-bit mode, the address byte is store in RADDR[7:0]</li> <li>In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0]</li> </ul> |

## 52.4.1.27 Slave Transmit ACK Register (STAR)

### 52.4.1.27.1 Offset

| Register | Offset |
|----------|--------|
| STAR     | 154h   |

### 52.4.1.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL]).

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

### 52.4.1.27.4 Fields

| Field       | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1<br>—   | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0<br>TXNACK | Transmit NACK<br>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK. <ul style="list-style-type: none"> <li>• When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).</li> <li>• To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.</li> </ul><br>0b - Write a Transmit ACK for each received word<br>1b - Write a Transmit NACK for each received word |

## 52.4.1.28 Slave Transmit Data Register (STDR)

### 52.4.1.28.1 Offset

| Register | Offset |
|----------|--------|
| STDR     | 160h   |

### 52.4.1.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

## Chapter 53

# Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

## 53.1 Chip-specific LPUART information

### 53.1.1 Instantiation Information

The LPUART module supports basic UART with DMA interface function and  $\times 4$  to  $\times 32$  oversampling of baud-rate. The following tables summarize the implementation of this module for each chip in the product series.

**Table 53-1. LPUART instances and features**

| Chip     | Instances | TX FIFO (word) | RX FIFO (word) |
|----------|-----------|----------------|----------------|
| S32K116  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
| S32K118  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
| S32K142  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
| S32K144  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
|          | LPUART2   | 4              | 4              |
| S32K144W | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
|          | LPUART2   | 4              | 4              |
| S32K146  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
|          | LPUART2   | 4              | 4              |
| S32K148  | LPUART0   | 4              | 4              |
|          | LPUART1   | 4              | 4              |
|          | LPUART2   | 4              | 4              |

This module supports LIN master and slave operation.

Low leakage and Wait mode is not supported in this device. RTS and CTS features are not supported to used in VLPS mode. See [Module operation in available power modes](#) for details on available power modes.

## 53.2 Introduction

### 53.2.1 Features

Features of the LPUART module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Transmit and receive baud rate can operate asynchronous to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in Stop modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Three receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit break character generation / 11-bit break character detection
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64 or 128 idle characters

- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

## 53.2.2 Modes of operation

### 53.2.2.1 Stop mode

The LPUART remains functional during Stop mode, provided the CTRL[DOZEEN] bit is clear and the asynchronous transmit and receive clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.

If the LPUART is disabled in Stop mode, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

### 53.2.2.2 Debug mode

The LPUART remains functional in debug mode.

## 53.2.3 Signal Descriptions

| Signal | Description                                                                                                                                                                               | I/O |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| TXD    | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| RXD    | Receive data.                                                                                                                                                                             | I   |
| CTS_B  | Clear to send.                                                                                                                                                                            | I   |
| RTS_B  | Request to send.                                                                                                                                                                          | O   |

## 53.2.4 Block diagram

The following figure shows the transmitter portion of the LPUART.

**Figure 53-1. LPUART transmitter block diagram**

The following figure shows the receiver portion of the LPUART.

Figure 53-2. LPUART receiver block diagram

## 53.3 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map generates a bus error.

### NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 53.3.1 LPUART register descriptions

### 53.3.1.1 LPUART memory map

|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p><b>NOTE:</b> The LBKDE bit enables the LIN break detect circuit and disables writing receive data to FIFO. So it essentially ignores all characters except a LIN break.</p> <p>0b - LIN break detect is disabled, normal break character can be detected.</p> <p>1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 24<br>RAF  | <p>Receiver Active Flag</p> <p>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.</p> <p>0b - LPUART receiver idle waiting for a start bit.</p> <p>1b - LPUART receiver active (RXD input not idle).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 23<br>TDRE | <p>Transmit Data Register Empty Flag</p> <p>When the transmit FIFO is enabled, TDRE is set when the number of datawords in the transmit FIFO (DATA register) is equal to or less than the number indicated by WATER[TXWATER]. To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE is set when the transmit DATA register is empty. To clear TDRE, write to the DATA register.</p> <p>TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character.</p> <p>0b - Transmit data buffer full.</p> <p>1b - Transmit data buffer empty.</p>                                                                                                                                                                                                                                                                                                 |
| 22<br>TC   | <p>Transmission Complete Flag</p> <p>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK].</p> <p>0b - Transmitter active (sending data, a preamble, or a break).</p> <p>1b - Transmitter idle (transmission activity complete).</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| 21<br>RDRF | <p>Receive Data Register Full Flag</p> <p>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive data buffer is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register.</p> <p>A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character continues to be received until an overrun condition occurs once the entire character is received.</p> <p>0b - Receive data buffer empty.</p> <p>1b - Receive data buffer full.</p>                                                                                                                                                                                  |
| 20<br>IDLE | <p>Idle Line Flag</p> <p>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.</p> <p>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag. IDLE is set only once even if the receive line remains idle for an extended period.</p> |

## Register definition

| Field      | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p>0b - No idle line detected.<br/>1b - Idle line was detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 19<br>OR   | <p>Receiver Overrun Flag</p> <p>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.</p> <p>While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.</p> <p>0b - No overrun.<br/>1b - Receive overrun (new LPUART data lost).</p> |
| 18<br>NF   | <p>Noise Flag</p> <p>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register was received with noise detected within the character. To clear NF, write logic 1 to the NF field.</p> <p>0b - No noise detected.<br/>1b - Noise detected in the received character in the DATA register.</p>                                                                                                                                                                                                                                                                      |
| 17<br>FE   | <p>Framing Error Flag</p> <p>FE is set whenever the next character to be read from the DATA register was received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field.</p> <p>0b - No framing error detected. This does not guarantee the framing is correct.<br/>1b - Framing error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 16<br>PF   | <p>Parity Error Flag</p> <p>PF is set whenever the next character to be read from the DATA register was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field.</p> <p>0b - No parity error.<br/>1b - Parity error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 53.3.1.8 LPUART Control Register (CTRL)

#### 53.3.1.8.1 Offset

| Register | Offset |
|----------|--------|
| CTRL     | 18h    |

#### 53.3.1.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

|             | 1b - Hardware interrupt requested when IDLE flag is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 19<br>TE    | <p>Transmitter Enable</p> <p>Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit reads as 1 until the transmitter has completed the current character and the TXD pin is tristated.</p> <p>A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.</p> <p>0b - Transmitter disabled.<br/>1b - Transmitter enabled.</p>                                                                                                                                                                                                                                                                                                                                        |
| 18<br>RE    | <p>Receiver Enable</p> <p>Enables the LPUART receiver. When RE is written to 0, this register bit reads as 1 until the receiver finishes receiving the current character (if any).</p> <p>0b - Receiver disabled.<br/>1b - Receiver enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 17<br>RWU   | <p>Receiver Wakeup Control</p> <p>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.</p> <p><b>NOTE:</b> RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.</p> <p>0b - Normal receiver operation.<br/>1b - LPUART receiver in standby waiting for wakeup condition.</p> |
| 16<br>SBK   | <p>Send Break</p> <p>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.</p> <p>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.</p> <p>0b - Normal transmitter operation.<br/>1b - Queue break character(s) to be sent.</p>                                                                                                                                                             |

When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.<br>1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input.                                                                                                                                                                                                                                                                                                             |
| 4<br>M      | 9-Bit or 8-Bit Mode Select<br>0b - Receiver and transmitter use 8-bit data characters.<br>1b - Receiver and transmitter use 9-bit data characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3<br>WAKE   | Receiver Wakeup Method Select<br>Determines which condition wakes the LPUART when RWU=1:<br><ul style="list-style-type: none"> <li>Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or</li> <li>An idle condition on the receive pin input signal.</li> </ul> 0b - Configures RWU for idle-line wakeup.<br>1b - Configures RWU with address-mark wakeup.                                                                                                                                                                                                                                                                                               |
| 2<br>ILT    | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br><b>NOTE:</b> In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - Idle character bit count starts after start bit.<br>1b - Idle character bit count starts after stop bit. |
| 1<br>PE     | Parity Enable<br>Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - No hardware parity generation or checking.<br>1b - Parity enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 0     | Parity Type                                                                                                                                                                                                                                                                                                                        |
| PT    | <p>Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.</p> <p>0b - Even parity.<br/>1b - Odd parity.</p> |

### 53.3.1.9 LPUART Data Register (DATA)

#### 53.3.1.9.1 Offset

| Register | Offset |
|----------|--------|
| DATA     | 1Ch    |

#### 53.3.1.9.2 Function

##### NOTE

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

| 9-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match.<br><br>This field should only be changed when the receiver is disabled. |

|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | 1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full.                                                                                                                                                                                                                                                              |
| 2<br>TXRTSPOL | Transmitter request-to-send polarity<br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS remains negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.<br>0b - Transmitter RTS is active low.<br>1b - Transmitter RTS is active high.                                                                                                                                                                                                           |
| 1<br>TXRTSE   | Transmitter request-to-send enable<br>Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.<br>0b - The transmitter has no effect on RTS.<br>1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit.                                                                              |
| 0<br>TXCTSE   | Transmitter clear-to-send enable<br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br>0b - CTS has no effect on the transmitter.<br>1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

## 53.3.1.12 LPUART FIFO Register (FIFO)

### 53.3.1.12.1 Offset

| Register | Offset |
|----------|--------|
| FIFO     | 28h    |

### 53.3.1.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

| RXUF              | Indicates that more data has been read from the receive buffer than was present. This field asserts regardless of the value of RXUFE. However, an interrupt is issued to the host only if RXUFE is set. This flag is cleared by writing a 1.<br>0b - No receive buffer underflow has occurred since the last time the flag was cleared.<br>1b - At least one receive buffer underflow has occurred since the last time the flag was cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15<br>TXFLUSH     | Transmit FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.<br>0b - No flush operation occurs.<br>1b - All data in the transmit FIFO/Buffer is cleared out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 53.3.1.13 LPUART Watermark Register (WATER)

#### 53.3.1.13.1 Offset

| Register | Offset |
|----------|--------|
| WATER    | 2Ch    |

#### 53.3.1.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

| Field            | Function                                                                                                                                                                                                                                                                                                                                                         |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27<br>—       | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 26-24<br>RXCOUNT | Receive Counter<br>The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.        |
| 23-18<br>—       | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 17-16<br>RXWATER | Receive Watermark<br>When the number of datawords in the receive FIFO/buffer is greater than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].                                  |
| 15-11<br>—       | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 10-8<br>TXCOUNT  | Transmit Counter<br>The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with FIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer. |
| 7-2<br>—         | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 1-0              | Transmit Watermark                                                                                                                                                                                                                                                                                                                                               |

| Field   | Function                                                                                                                                                                                                                                                                                                                          |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXWATER | When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt or a DMA request is generated. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE]. |

## 53.4 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

### 53.4.1 Clocking and Resets

**Table 53-2. Clocks**

|                         |                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPUART Functional clock | The LPUART functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support transmit and/or receive, including low power wakeups.                                                                          |
| Bus clock               | The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs. |

**Table 53-3. Resets**

|                |                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chip reset     | The logic and registers for the LPUART transmitter and receiver are reset to their default state on a chip reset.                                                       |
| Software reset | Resets the LPUART logic and registers to their default state, except for the Global Register. The LPUART software reset is in the Global Register GLOBAL[RST].          |
| FIFO reset     | The LPUART implements write-only control bits that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO is empty. |

### 53.4.2 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio. Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

**Figure 53-3. LPUART baud rate generation**

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled, each transmitted character aligns to the next edge of the transmit bit clock.

### 53.4.3 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high, CTRL[TXINV] is cleared following reset. The transmitter output is inverted by setting CTRL[TXINV]. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13 bits long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the

transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at the DATA register.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter does not start transmitting another character.

### 53.4.3.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with bit 13 set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with bit 13 set and the data bits also set. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

**Table 53-4. Break character length**

| BRK13 | M | M10 | M7 | SNBS | Break character length |
|-------|---|-----|----|------|------------------------|
| 0     | 0 | 0   | 0  | 0    | 10 bit times           |
| 0     | 0 | 0   | 0  | 1    | 11 bit times           |
| 0     | 0 | 0   | 1  | 0    | 9 bit times            |
| 0     | 0 | 0   | 1  | 1    | 10 bit times           |
| 0     | 1 | 0   | X  | 0    | 11 bit times           |
| 0     | 1 | 0   | X  | 1    | 12 bit times           |
| 0     | X | 1   | X  | 0    | 12 bit times           |
| 0     | X | 1   | X  | 1    | 13 bit times           |
| 1     | 0 | 0   | 0  | 0    | 13 bit times           |
| 1     | 0 | 0   | 0  | 1    | 13 bit times           |
| 1     | 0 | 0   | 1  | 0    | 12 bit times           |
| 1     | 0 | 0   | 1  | 1    | 12 bit times           |
| 1     | 1 | 0   | X  | 0    | 14 bit times           |
| 1     | 1 | 0   | X  | 1    | 14 bit times           |
| 1     | X | 1   | X  | 0    | 15 bit times           |
| 1     | X | 1   | X  | 1    | 15 bit times           |

### 53.4.3.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS\_B. If the clear-to-send operation is enabled, the character is transmitted when CTS\_B is asserted. If CTS\_B is deasserted in the middle of a transmission with characters remaining in the transmitter data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS\_B is reasserted. The CTS\_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS\_B.

The transmitter's CTS\_B signal can also be enabled even if the same LPUART receiver's RTS\_B signal is disabled.

### 53.4.3.3 Transceiver driver enable

The transmitter can use RTS\_B as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using RTS\\_B](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS\_B asserts one bit time before the start bit is transmitted. RTS\_B remains asserted for the whole time that the transmitter data buffer has any characters. RTS\_B deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS\_B, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS\_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS\_B signal is unaffected by its CTS\_B signal. RTS\_B remains asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

### 53.4.3.4 Transceiver driver enable using RTS\_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS\_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS\_B can be matched to the polarity of the transceiver's driver enable signal.

**Figure 53-4. Transceiver driver enable using RTS\_B**

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS\_B to both DE and RE\_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

### 53.4.4 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to [Data Modes](#). For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the LPUART receiver is double-buffered, the program has one full character time after [RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to [Interrupts and status flags](#) for details about flag clearing.

#### 53.4.4.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any

sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive data buffer.

When the LPUART receiver is configured to sample on both edges of the baud rate clock, the number of segments in each received bit is effectively doubled (from 1 to  $OSR \times 2$ ). The start and data bits are then sampled at  $OSR$ ,  $OSR+1$  and  $OSR+2$ . Sampling on both edges of the clock must be enabled for oversampling rates of  $4\times$  to  $7\times$  and is optional for higher oversampling rates.

The "synchronization" is a feature of the LPUART module to synchronize the internal oversampling counter with detected falling edge on Rx signal, and to adjust the data sampling window. The falling edge detection needs three consecutive '1' prior to '1'-'0' transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter once another falling edge is detected. This is called "resynchronization".

- When LPUART\_BAUD[RESYNCDIS] = 0, this falling edge detection and resynchronization is performed not only for the start bit but also for the rest of character reception after the start bit.
- When LPUART\_BAUD[RESYNCDIS] = 1, the falling edge detection and resynchronization is performed only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

See the following table and figure.

**Table 53-5. LPUART  
resynchronization**

| Resynchronization                           | LPUART_BAUD[RESYNCDIS]=0 | LPUART_BAUD[RESYNCDIS]=1 |
|---------------------------------------------|--------------------------|--------------------------|
| For the starting bit falling edge           | Yes                      | Yes                      |
| For every falling edges after the start bit | Yes                      | No                       |

Figure 53-5. LPUART resynchronization

### 53.4.4.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 53-6. Receiver Wakeup Options

| RWU | MA1   MA2 | MATCFG | WAKE:RWUID | Receiver Wakeup  |
|-----|-----------|--------|------------|------------------|
| 0   | 0         | X      | X          | Normal operation |

Table continues on the next page...

**Table 53-6. Receiver Wakeup Options (continued)**

| RWU | MA1   MA2 | MATCFG | WAKE:RWUID | Receiver Wakeup                                                                    |
|-----|-----------|--------|------------|------------------------------------------------------------------------------------|
| 1   | 0         | 00     | 00         | Receiver wakeup on idle line, IDLE flag not set                                    |
| 1   | 0         | 00     | 01         | Receiver wakeup on idle line, IDLE flag set                                        |
| 1   | 0         | 00     | 10         | Receiver wakeup on address mark                                                    |
| 1   | 1         | 11     | 10         | Receiver wakeup on data match                                                      |
| 0   | 1         | 00     | X0         | Address mark address match, IDLE flag not set for discarded characters             |
| 0   | 1         | 00     | X1         | Address mark address match, IDLE flag set for discarded characters                 |
| 0   | 1         | 01     | X0         | Idle line address match                                                            |
| 0   | 1         | 10     | X0         | Address match on and address match off, IDLE flag not set for discarded characters |
| 0   | 1         | 10     | X1         | Address match on and address match off, IDLE flag set for discarded characters     |

#### 53.4.4.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7] and BAUD[M10] control bit selects 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is one and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line. When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

#### 53.4.4.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

#### 53.4.4.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

#### 53.4.4.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs then no transfer is made to the receive data buffer, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

#### 53.4.4.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive data buffer until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive data buffer, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

#### 53.4.4.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive data buffer, until a character

is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

#### NOTE

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

### 53.4.4.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS\_B.

- RTS\_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using RTS\\_B](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS\_B if the number of characters in the receiver data register is full or a start bit is detected that causes the receiver data register to be full.
- The receiver asserts RTS\_B when the number of characters in the receiver data register is not full and has not detected a start bit that causes the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
- Even if RTS\_B is deasserted, the receiver continues to receive characters until the receiver data buffer is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS\_B remains deasserted.

### 53.4.4.4 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received.

#### 53.4.4.4.1 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the

receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 53.4.4.4.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

#### 53.4.4.4.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

#### 53.4.4.4.4 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

### 53.4.5 Additional LPUART functions

The following sections describe additional LPUART functions.

#### 53.4.5.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit. For the transmit data buffer, these bits are stored in CTRL[T8] and CTRL[T9]. For the receiver, these bits are held in CTRL[R8] and CTRL[R9]. They are also accessible via 16-bit or 32-bit accesses to the DATA register.

For coherent 8-bit writes to the transmit data buffer, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0]. For 16-bit and 32-bit writes to the DATA register, all 10 transmit bits are written to the transmit data buffer at the same time.

If the bit values to be transmitted as the ninth and tenth bit of a new character are the same as for the previous character, it is not necessary to write to CTRL[T8] and CTRL[T9] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in CTRL[T8] and CTRL[T9] is copied at the same time data is transferred from DATA[7:0] to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

### **53.4.5.2 Idle length**

An idle character is a character where the start bit, all data bits and stop bits are in the mark position. The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit causes any discarded characters to be treated as if they were idle characters.

### **53.4.5.3 Loop mode**

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

### 53.4.5.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

### 53.4.6 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This module covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the LPUART. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

### 53.4.6.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of  $1/OSR$ ,  $2/OSR$ ,  $3/OSR$ , or  $4/OSR$  of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

### 53.4.6.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

## 53.4.7 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty (STAT[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to the DATA register. If the transmit interrupt enable (CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error was detected in the received character that caused STAT[RDRF] to be set, the error flags - noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) - are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (STAT[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

## 53.4.8 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

### 53.4.8.1 Output Triggers

The LPUART generates the following output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts at when the idle flag would set, for one oversampling clock period.

### 53.4.8.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

## Functional description

- The input trigger can be connected in place of the CTS\_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be generated from a PWM source with a period that is less than the bit clock frequency.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

# Chapter 54

## Flexible I/O (FlexIO)

### 54.1 Chip-specific FlexIO information

#### 54.1.1 FlexIO Configuration

Table 54-1. FlexIO Configuration

|        | Timers | Shifters | Pins |
|--------|--------|----------|------|
| Number | 4      | 4        | 8    |

Low leakage and Wait mode is not supported in this device. See [Module operation in available power modes](#) for details on available power modes.

#### NOTE

Accessing FlexIO registers with FlexIO peripheral clock (FlexIO clock) disabled will result in transfer error or stall the bus.

### 54.2 Introduction

#### 54.2.1 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions

## 54.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- PWM/Waveform generation

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive and data match modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions

## 54.2.3 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

Figure 54-1. FlexIO block diagram

## 54.2.4 Modes of operation

The FlexIO module supports the chip modes described in the following table.

Table 54-2. Chip modes supported by the FlexIO module

| Chip mode | FlexIO Operation                                                          |
|-----------|---------------------------------------------------------------------------|
| Run       | Normal operation                                                          |
| Debug     | Can continue operating provided the Debug Enable bit (CTRL[DBGE]) is set. |

## 54.2.5 FlexIO Signal Descriptions

| Signal            | Description                                               | I/O |
|-------------------|-----------------------------------------------------------|-----|
| FXIO_Dn (n=0...7) | Bidirectional FlexIO Shifter and Timer pin inputs/outputs | I/O |

## 54.3 Memory Map and Registers

### 54.3.1 FLEXIO register descriptions

#### NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register or accessing an invalid address.

#### 54.3.1.1 FLEXIO memory map

FlexIO base address: 4005\_A000h

| Offset      | Register                                                                     | Width<br>(In bits) | Access | Reset value |
|-------------|------------------------------------------------------------------------------|--------------------|--------|-------------|
| 0h          | Version ID Register (VERID)                                                  | 32                 | RO     | 0101_0000h  |
| 4h          | Parameter Register (PARAM)                                                   | 32                 | RO     | 0408_0404h  |
| 8h          | FlexIO Control Register (CTRL)                                               | 32                 | RW     | 0000_0000h  |
| Ch          | Pin State Register (PIN)                                                     | 32                 | RO     | 0000_0000h  |
| 10h         | Shifter Status Register (SHIFTSTAT)                                          | 32                 | W1C    | 0000_0000h  |
| 14h         | Shifter Error Register (SHIFTEERR)                                           | 32                 | W1C    | 0000_0000h  |
| 18h         | Timer Status Register (TIMSTAT)                                              | 32                 | W1C    | 0000_0000h  |
| 20h         | Shifter Status Interrupt Enable (SHIFTSIEN)                                  | 32                 | RW     | 0000_0000h  |
| 24h         | Shifter Error Interrupt Enable (SHIFTEIEN)                                   | 32                 | RW     | 0000_0000h  |
| 28h         | Timer Interrupt Enable Register (TIMIEN)                                     | 32                 | RW     | 0000_0000h  |
| 30h         | Shifter Status DMA Enable (SHIFTSDEN)                                        | 32                 | RW     | 0000_0000h  |

## 54.3.1.13 Shifter Control N Register (SHIFTCTL0 - SHIFTCTL3)

### 54.3.1.13.1 Offset

| Register  | Offset |
|-----------|--------|
| SHIFTCTL0 | 80h    |
| SHIFTCTL1 | 84h    |
| SHIFTCTL2 | 88h    |
| SHIFTCTL3 | 8Ch    |

### 54.3.1.15 Shifter Buffer N Register (SHIFTBUF0 - SHIFTBUF3)

#### 54.3.1.15.1 Offset

| Register  | Offset |
|-----------|--------|
| SHIFTBUF0 | 200h   |
| SHIFTBUF1 | 204h   |
| SHIFTBUF2 | 208h   |
| SHIFTBUF3 | 20Ch   |

#### 54.3.1.15.2 Diagram

#### 54.3.1.15.3 Fields

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>SHIFTBUF | <p>Shift Buffer</p> <p>Shift buffer data is used for a variety of functions depending on the SMOD setting:</p> <p>For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available.</p> <p>For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins.</p> <p>For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available.</p> <p>For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask).</p> |

### 54.3.1.16 Shifter Buffer N Bit Swapped Register (SHIFTBUFBIS0 - SHIFTBUFBIS3)

#### 54.3.1.16.1 Offset

| Register     | Offset |
|--------------|--------|
| SHIFTBUFBIS0 | 280h   |
| SHIFTBUFBIS1 | 284h   |
| SHIFTBUFBIS2 | 288h   |
| SHIFTBUFBIS3 | 28Ch   |

#### 54.3.1.16.2 Diagram

#### 54.3.1.16.3 Fields

| Field       | Function                                                                                                       |
|-------------|----------------------------------------------------------------------------------------------------------------|
| 31-0        | Shift Buffer                                                                                                   |
| SHIFTBUFBIS | Alias to SHIFTBUF register, except reads/writes to this register are bit swapped. Reads return SHIFTBUF[0:31]. |

### 54.3.1.17 Shifter Buffer N Byte Swapped Register (SHIFTBUFBYS0 - SHIFTBUFBYS3)

### 54.3.1.17.1 Offset

| Register     | Offset |
|--------------|--------|
| SHIFTBUFBYS0 | 300h   |
| SHIFTBUFBYS1 | 304h   |
| SHIFTBUFBYS2 | 308h   |
| SHIFTBUFBYS3 | 30Ch   |

### 54.3.1.20 Timer Configuration N Register (TIMCFG0 - TIMCFG3)

### 54.3.1.20.1 Offset

| Register | Offset |
|----------|--------|
| TIMCFG0  | 480h   |
| TIMCFG1  | 484h   |
| TIMCFG2  | 488h   |
| TIMCFG3  | 48Ch   |

### 54.3.1.20.2 Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

#### NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

## 54.4 Functional description

### 54.4.1 Clocking and Resets

#### 54.4.1.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least two times faster than the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

### 54.4.1.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

### 54.4.1.3 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

### 54.4.1.4 Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[RST] will reset all logic and registers to their default state, except for the CTRL itself.

## 54.4.2 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

**Figure 54-2. Shifter Microarchitecture**

### 54.4.2.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter will load data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after SHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Note that the shifter will immediately load a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag will clear when new data has been written into the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

### 54.4.2.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter will shift data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

### 54.4.2.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter will shift data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop

bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the matched data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

#### 54.4.2.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter will shift data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs. The flag will clear automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register.

The Shifter Error Flag (SHIFTErr[SEF]) and any enabled interrupts will set when a match occurs. The flag will clear when there is a read from the SHIFTBUF register or it is written with logic 1.

### 54.4.3 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

### **54.4.3.1 Timer 8-bit Baud Counter Mode**

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode will only reset the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### **54.4.3.2 Timer 8-bit High PWM Mode**

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 54.4.3.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

### 54.4.3.4 Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur.

- Timer counter will load the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer will either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter will reload with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

### 54.4.3.5 Timer Decrement and Reset

The Timer will then generate the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer will decrement on both rising and falling edges.

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter will load the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event will cause the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

#### **54.4.3.6 Timer Disable and Stop Bit**

When the is Timer is configured to add a stop bit on each compare, the following additional events will occur.

- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter will reload the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter will reload the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output will clear. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter will continue decrementing until the next rising edge of the shift clock is detected, at which point it will finish. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers with stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

### 54.4.4 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

#### 54.4.4.1 Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin will make an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

## 54.4.5 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

**Table 54-3. FlexIO Interrupts and DMA Requests**

| Flag | Description          | Interrupt | DMA Request | Low Power Wakeup |
|------|----------------------|-----------|-------------|------------------|
| SSF  | Shifter Status Flag. | Y         | Y           | Y                |
| SEF  | Shifter Error Flag.  | Y         | N           | Y                |
| TSF  | Timer Status Flag.   | Y         | N           | Y                |

## 54.4.6 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

### 54.4.6.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

### 54.4.6.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

## 54.5 Application Information

This section provides examples for a variety of FlexIO module applications.

### 54.5.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUF<sub>n</sub> (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

**Table 54-4. UART Transmit Configuration**

| Register              | Value       | Comments                                                                                                                                                                                  |
|-----------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFG <sub>n</sub> | 0x0000_0032 | Configure start bit of 0 and stop bit of 1.                                                                                                                                               |
| SHIFTCTL <sub>n</sub> | 0x0003_0002 | Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1. |
| TIMCMP <sub>n</sub>   | 0x0000_0F01 | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.                   |
| TIMCFG <sub>n</sub>   | 0x0000_2222 | Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3.                                                               |
| TIMCTL <sub>n</sub>   | 0x01C0_0001 | Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1.                       |

*Table continues on the next page...*

**Table 54-4. UART Transmit Configuration (continued)**

| Register              | Value            | Comments                                                                                                                                                                                                                                                      |
|-----------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTBUF <sub>n</sub> | Data to transmit | Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead. |

## 54.5.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters will cause the error flag to set and the shifter buffer register will return 0x00.

FlexIO does not support automatic verification of parity bits.

**Table 54-5. UART Receiver Configuration**

| Register              | Value       | Comments                                                                                                                                                                |
|-----------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFG <sub>n</sub> | 0x0000_0032 | Configure start bit of 0 and stop bit of 1.                                                                                                                             |
| SHIFCTL <sub>n</sub>  | 0x0080_0001 | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.                                                  |
| TIMCMP <sub>n</sub>   | 0x0000_0F01 | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFG <sub>n</sub>   | 0x0204_2422 | Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.                  |
| TIMCTL <sub>n</sub>   | 0x0000_0081 | Configure dual 8-bit counter using inverted Pin 0 input.                                                                                                                |

**Table 54-5. UART Receiver Configuration (continued)**

| Register              | Value           | Comments                                                                                                                                                                                                                            |
|-----------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTBUF <sub>n</sub> | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.<br>Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS will assert when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit will be detected while the RTS is asserted, the received data is simply ignored.

**Table 54-6. UART Receiver with RTS Configuration**

| Register                | Value           | Comments                                                                                                                                                                                                                            |
|-------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFG <sub>n</sub>   | 0x0000_0032     | Configure start bit of 0 and stop bit of 1.                                                                                                                                                                                         |
| SHIFTCTL <sub>n</sub>   | 0x0080_0001     | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.                                                                                                              |
| TIMCMP <sub>n</sub>     | 0x0000_0F01     | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.                                                             |
| TIMCFG <sub>n</sub>     | 0x0204_2522     | Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4.                                                        |
| TIMCTL <sub>n</sub>     | 0x02C0_0081     | Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.                                                                                                                            |
| TIMCMP <sub>(n+1)</sub> | 0x0000_FFFF     | Never compare.                                                                                                                                                                                                                      |
| TIMCFG <sub>(n+1)</sub> | 0x0030_6100     | Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.                                                                                                                            |
| TIMCTL <sub>(n+1)</sub> | 0x0143_0003     | Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.                                                                                                                                             |
| SHIFTBUF <sub>n</sub>   | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.<br>Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

### 54.5.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 54-7. SPI Master (CPHA=0) Configuration**

| Register      | Value            | Comments                                                                                                                                                                 |
|---------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTCFGn     | 0x0000_0000      | Start and stop bit disabled.                                                                                                                                             |
| SHIFTCTLn     | 0x0083_0002      | Configure transmit using Timer 0 on negedge of clock with output data on Pin 0.                                                                                          |
| SHIFTCFG(n+1) | 0x0000_0000      | Start and stop bit disabled.                                                                                                                                             |
| SHIFTCTL(n+1) | 0x0000_0101      | Configure receive using Timer 0 on posedge of clock with input data on Pin 1.                                                                                            |
| TIMCMPn       | 0x0000_3F01      | Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn       | 0x0100_2222      | Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.                                                            |
| TIMCTLn       | 0x01C3_0201      | Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock.                 |
| TIMCMP(n+1)   | 0x0000_FFFF      | Never compare.                                                                                                                                                           |
| TIMCFG(n+1)   | 0x0000_1100      | Enable when Timer 0 is enabled and disable when Timer 0 is disabled.                                                                                                     |
| TIMCTL(n+1)   | 0x0003_0383      | Configure 16-bit counter (never compare) using inverted Pin 3 output (as slave select).                                                                                  |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to SHIFTBUF, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can                           |

### 54.5.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

**Table 54-9. SPI Slave (CPHA=0) Configuration**

| Register      | Value            | Comments                                                                                                                                       |

## 54.5.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter will load 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register will assert an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

| TIMCMPn       | 0x0000_2501      | Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set $TIMCMP[15:8] = (\text{number of words} \times 18) + 1$ . Set $TIMCMP[7:0] = (\text{baud rate divider} / 2) - 1$ . |
| TIMCFGn       | 0x0102_2222      | Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.                                 |
| TIMCTLn       | 0x01C1_0101      | Configure dual 8-bit counter using Pin 1 output enable (SCL open drain), with Shifter 0 flag as the inverted trigger.                                                                               |
| TIMCMP(n+1)   | 0x0000_000F      | Configure 8-bit transfer. Set $TIMCMP[15:0] = (\text{number of bits} \times 2) - 1$ .                                                                                                               |
| TIMCFG(n+1)   | 0x0020_1112      | Enable when Timer 0 is enabled, disable when Timer 0 is disabled, enable start bit and stop bit at end of each word, decrement on pin input.                                                        |
| TIMCTL(n+1)   | 0x01C0_0183      | Configure 16-bit counter using inverted Pin 1 input (SCL).                                                                                                                                          |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to $SHIFTBUFBBS[7:0]$ , use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.                                               |
| SHIFTBUF(n+1) | Data to receive  | Received data can be read from $SHIFTBUFBIS[7:0]$ , use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.                                                   |

### 54.5.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before

enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

| TIMCFGn       | 0x0000_0202      | Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.                                                                                                                        |
| TIMCTLn       | 0x01C3_0201      | Configure dual 8-bit counter using Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock.                                                                |
| TIMCMP(n+1)   | 0x0000_007F      | Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.                                                                             |
| TIMCFG(n+1)   | 0x0000_0100      | Enable when Timer 0 is enabled and never disable.                                                                                                                                                                     |
| TIMCTL(n+1)   | 0x0003_0383      | Configure 16-bit counter using inverted Pin 3 output (as frame sync).                                                                                                                                                 |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead. |

*Table continues on the next page...*

**Table 54-12. I2S Master Configuration (continued)**

| Register      | Value           | Comments                                                                                                                                                                                                           |
|---------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIFTBUF(n+1) | Data to receive | Received data can be read from SHIFTBUFBS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead. |

### 54.5.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until falling edge of bit clock (when frame sync is normally sampled). Timer 0 detects falling edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects rising edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

**Table 54-13. I2S Slave Configuration**

| Register      | Value       | Comments                                                                                  |
|---------------|-------------|-------------------------------------------------------------------------------------------|
| SHIFTCFGn     | 0x0000_0000 | Start and stop bit disabled.                                                              |
| SHIFTCTLn     | 0x0103_0002 | Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0. |
| SHIFTCFG(n+1) | 0x0000_0000 | Start and stop bit disabled.                                                              |
| SHIFTCTL(n+1) | 0x0180_0101 | Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.  |
| TIMCMPn       | 0x0000_007F | Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.    |

*Table continues on the next page...*

**Table 54-13. I2S Slave Configuration (continued)**

| Register      | Value            | Comments                                                                                                                                                                                                              |
|---------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIMCFGn       | 0x0020_2500      | Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).                                   |
| TIMCTLn       | 0x0B40_0283      | Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 2 output as the trigger.                                                                                                                  |
| TIMCMP(n+1)   | 0x0000_003F      | Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.                                                                                                                                              |
| TIMCFG(n+1)   | 0x0020_2500      | Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare, initial clock state is logic 1 and decrement on pin input (bit clock).                                            |
| TIMCTL(n+1)   | 0x0340_0283      | Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.                                                                                                                  |
| TIMCMP(n+2)   | 0x0000_0000      | Compare on zero (first edge).                                                                                                                                                                                         |
| TIMCFG(n+2)   | 0x0020_6400      | Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock), initial clock state is logic 1 and decrement on inverted pin input (frame sync).                           |
| TIMCTL(n+2)   | 0x0440_0383      | Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 input (bit clock) as the trigger.                                                                                                        |
| SHIFTBUFn     | Data to transmit | Transmit data can be written to SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support LSB first transfer by writing to SHIFTBUF register instead. |
| SHIFTBUF(n+1) | Data to receive  | Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead.   |

# Chapter 55

## FlexCAN

### 55.1 Chip-specific FlexCAN information

#### 55.1.1 Instantiation information

The following table summarizes the implementation of this module for each chip in the product series.

**Table 55-1. FlexCAN instances and features**

| Chip     | Instances | Number of Message Buffers (MB) | ISO CAN FD feature <sup>1</sup> | PNET feature | External time tick | CTRL2 register <sup>2</sup> reset value |
|----------|-----------|--------------------------------|---------------------------------|--------------|--------------------|-----------------------------------------|
| S32K116  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
| S32K118  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
| S32K142  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
|          | FlexCAN1  | 16 MBs                         | No                              | No           | No                 | 0x00B0_0000                             |
| S32K144  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
|          | FlexCAN1  | 16 MBs                         | No                              | No           | No                 | 0x00B0_0000                             |
|          | FlexCAN2  | 16 MBs                         | No                              | No           | No                 | 0x00B0_0000                             |
| S32K14xW | FlexCAN0  | 64 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
|          | FlexCAN1  | 64 MBs                         | Yes                             | No           | No                 | 0x00A0_0000                             |
| S32K146  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
|          | FlexCAN1  | 32 MBs                         | Yes                             | No           | No                 | 0x00A0_0000                             |
|          | FlexCAN2  | 16 MBs                         | No                              | No           | No                 | 0x00B0_0000                             |
| S32K148  | FlexCAN0  | 32 MBs                         | Yes                             | Yes          | Yes                | 0x00A0_0000                             |
|          | FlexCAN1  | 32 MBs                         | Yes                             | No           | No                 | 0x00A0_0000                             |
|          | FlexCAN2  | 32 MBs                         | Yes                             | No           | No                 | 0x00A0_0000                             |

1. Refer to 10<sup>th</sup> character (Ordering Option Y) in orderable product part number for the availability of ISO CAN FD feature (for details see device datasheet). The entire number of Message Buffers are still available for the products with SIM\_SDID[6]=0 under CAN classical mode.
2. Bit fields CTRL2[PREXCEN] and CTRL2[EDFLTDIS] are implemented in instances supporting ISO CAN FD feature only.

## 55.1.2 FlexCAN register information

The [CAN memory map](#) shows a superset of registers implemented for the S32K1xx series. S32K14xW has some differences in register/register bit field implementation, which are listed in the following note. See the following sections for details.

### NOTE

- For S32K14xW, the address range from offset 0x80 to 0x47F allocates the sixty-four 128-bit message buffers (MBs).
- S32K14xW has two additional registers - [Interrupt Masks 2 register \(IMASK2\)](#) and [Interrupt Flags 2 register \(IFLAG2\)](#) - for FlexCAN0 and FlexCAN1 instances as described in the following sections.
- The [Rx Individual Mask registers \(RXIMR0 - RXIMR63\)](#) array ranges from 0 - 63 for S32K14xW.
- The [CAN FD Control register \(FDCTRL\)](#) in S32K14xW has an additional register bit field implemented - [MBDSR1](#).

### 55.1.2.1 Interrupt Masks 2 register (IMASK2)

#### 55.1.2.1.1 Offset

| Register | Offset |
|----------|--------|
| IMASK2   | 24h    |

#### 55.1.2.1.2 Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

### 55.1.2.1.3 Diagram

### 55.1.2.1.4 Fields

| Field              | Function                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>BUF63TO32M | Buffer MB i Mask<br>Each bit enables or disables the corresponding FlexCAN message buffer interrupt for MB63 to MB32.<br><b>NOTE:</b> Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set.<br>0b - The corresponding buffer interrupt is disabled.<br>1b - The corresponding buffer interrupt is enabled. |

## 55.1.2.2 Interrupt Flags 2 register (IFLAG2)

### 55.1.2.2.1 Offset

| Register | Offset |
|----------|--------|
| IFLAG2   | 2Ch    |

### 55.1.2.2.2 Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

### 55.1.2.2.3 Diagram

### 55.1.2.2.4 Fields

| Field      | Function                                                                                                                                                                                                                                                                           |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0       | Buffer MB i Interrupt                                                                                                                                                                                                                                                              |
| BUF63TO32I | Each bit flags the corresponding FlexCAN message buffer interrupt for MB63 to MB32.<br>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception.<br>1b - The corresponding buffer has successfully completed transmission or reception. |

## 55.1.2.3 Rx Individual Mask registers (RXIMR0 - RXIMR63)

### 55.1.2.3.1 Offset

For n = 0 to 63:

| Register | Offset          |
|----------|-----------------|
| RXIMRn   | 880h + (n × 4h) |

### 55.1.2.3.2 Function

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see [Rx FIFO](#)).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See [Bus interface](#) for more information.

### 55.1.2.3.3 Diagram

### 55.1.2.3.4 Fields

| 31-0  | Individual Mask Bits                                                                                                                                                                                                                                                                                                                                                                                                           |
| MI    | <p>Each individual mask bit masks the corresponding bit in both the mailbox filter and Rx FIFO ID filter table element in distinct ways.</p> <p>For mailbox filters, see the RXMGMASK register description.</p> <p>For Rx FIFO ID filter table elements, see the RXFGMASK register description.</p> <p>0b - The corresponding bit in the filter is "don't care."<br/> 1b - The corresponding bit in the filter is checked.</p> |

## 55.1.2.4 CAN FD Control register (FDCTRL)

### 55.1.2.4.1 Offset

| Register | Offset |
|----------|--------|
| FDCTRL   | C00h   |

### 55.1.2.4.2 Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

**Table 55-2. Number of message buffers**

| Payload size | Maximum number of message buffers per RAM block |
|--------------|-------------------------------------------------|
| 8 bytes      | 32                                              |
| 16 bytes     | 21                                              |
| 32 bytes     | 12                                              |
| 64 bytes     | 7                                               |

### NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

| 5-0<br>TDCVAL   | Transceiver Delay Compensation Value<br>This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK).<br>See <a href="#">Protocol timing</a> for more details on how the loop delay measurement is performed.                                                                                                                                                                                                                                                                 |

### 55.1.3 Reset value of MDIS bit

The CAN\_MCR[MDIS] bit is set after reset. Therefore, FlexCAN module is disabled following a reset.

### 55.1.4 FlexCAN external time tick

On this device, LPIT channel 0 trigger output acts as external time tick source for FlexCAN0.

### 55.1.5 FlexCAN Interrupts

The FlexCAN has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

**Table 55-3. FlexCAN Interrupts**

| Request          | For CAN with FD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | For CAN without FD                                                                                                                                                                                                                                                                  |

| Receive Warning  | Receive Warning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Receive Warning                                                                                                                                                                                                                                                                     |

### 55.1.6 FlexCAN Operation in Low Power Modes

The FlexCAN module is operational in VLPR mode. With the 4 MHz system clock (in VLPR mode), the fastest supported FlexCAN transfer rate is 250 kbps. The bit timing parameters in the module must be adjusted for the new frequency, but full functionality is possible.

See [Module operation in available power modes](#) for details on available power modes.

### 55.1.7 FlexCAN oscillator clock

FlexCAN oscillator clock is SOSCDIV2\_CLK as mentioned in section [Table 27-9](#)

### 55.1.8 Supported baud rate

The following table details the supported baud rate for each chip in the product series, considering payload of 8 bytes.

| Chip            | Number of MBs | PE clock frequency (MHz) | CHI clock frequency (MHz) | Maximum achievable baud rate (Mbps) |
|-----------------|---------------|--------------------------|---------------------------|-------------------------------------|
| S32K14x         | 32            | 16                       | 80                        | 3.2                                 |
|                 | 16            |                          |                           | 1                                   |
| S32K14x         | 32            | 80                       | 80                        | 8                                   |
|                 | 16            |                          |                           | 1                                   |
| S32K1xx (VLPR)  | 32            | 4                        | 4                         | 0.667                               |
|                 | 16            |                          |                           |                                     |
| S32K11x         | 32            | 16                       | 48                        | 3.2                                 |
|                 | 32            | 48                       |                           | 8                                   |
| S32K14xW        | 64            | 16                       | 80                        | 3.2                                 |
|                 |               | 80                       |                           | 8                                   |
| S32K14xW (VLPR) | 64            | 1                        | 1                         | 0.125                               |

### 55.1.9 Requirements for entering FlexCAN modes: Freeze, Disable, Stop

Follow the procedure described in [Freeze mode entry](#) to place the FlexCAN module in that mode.

On this chip, the FlexCAN module cannot directly enter:

- Module Disable mode
- Stop mode

To enter these modes, the FlexCAN module must first enter Freeze mode. To enter this mode, the FlexCAN module must first enter Freeze mode. See the following information about each of the modes.

### 55.1.9.1 Freeze mode entry

See [Freeze mode](#) for details about this mode.

On this chip, the procedure to enter Freeze mode is:

1. Set both CAN\_MCR[FRZ] (Freeze Enable) and CAN\_MCR[HALT] (Halt) to 1.
2. Check whether CAN\_MCR[MDIS] (Module Disable) is set to 1. If it is, clear it to 0.
3. Poll the MCR register until CAN\_MCR[FRZACK] (Freeze Mode Acknowledge) is set to 1 or the timeout is reached.

#### NOTE

The minimum timeout duration must be equivalent to:

- a. 730 CAN Nominal bits if CAN\_MCR[FDEN] (CAN FD Operation Enable) is set to 1 (CAN bits calculated at arbitration bit rate),
  - b. 180 CAN bits if CAN\_MCR[FDEN] is cleared to 0.
4. If CAN\_MCR[FRZACK] is set to 1, no further action is required. Skip steps 5 to 8.
  5. If the timeout is reached because CAN\_MCR[FRZACK] remains cleared to 0, then set CAN\_MCR[SOFTRST] (Soft Reset) to 1.
  6. Poll MCR until CAN\_MCR[SOFTRST] is cleared to 0.
  7. Reconfigure the Module Control register (CAN\_MCR).
  8. Reconfigure all the Interrupt Mask registers (CAN\_IMASK<sub>n</sub>).

After these steps are complete, the module is in Freeze mode.

### 55.1.9.2 Module Disable mode entry

See [Module Disable mode](#) for details about this mode.

**CAUTION**

In the detailed description of this mode, the list of FlexCAN behavior that begins with "If the module is disabled during transmission or reception" does not apply to this chip.

On this chip, the procedure to enter Module Disable mode is:

1. Enter Freeze mode by following the procedure described in [Freeze mode entry](#).
2. Request Module Disable mode by setting CAN\_MCR[MDIS] to 1.
3. Poll CAN\_MCR until CAN\_MCR[LPMACK] is set to 1. The minimum timeout duration for setting CAN\_MCR[LPMACK] is 2 CAN Nominal bits.

**55.1.9.3 Stop mode entry**

See [Stop mode](#) for details about this mode.

**CAUTION**

In the detailed description of this mode, the list of FlexCAN behavior that begins with "If Stop mode is requested during transmission or reception" does not apply to this chip.

On this chip, the procedure to enter Stop mode is:

1. Enter Freeze mode by following the procedure described in [Freeze mode entry](#).
2. Request Stop mode.
3. Poll MCR until CAN\_MCR[LPMACK] is set to 1. The minimum timeout duration for setting CAN\_MCR[LPMACK] is 2 CAN Nominal bits.

**55.2 Overview**

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the EMI environment of a vehicle. The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads.

**NOTE**

Rx FIFO cannot be used in FD mode.

## 55.2.1 Block diagram

A general block diagram is shown in [Figure 55-1](#), which describes the main subblocks implemented in the FlexCAN module.

**Figure 55-1. FlexCAN block diagram**

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

## 55.2.2 Features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 32 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes or matching with received frames (Pretended Networking)
- Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be managed automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames

- SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports Pretended Networking functionality in low power: Stop mode

### 55.3 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID filter table elements.

For Classical CAN frames, simultaneous reception through FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes only. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b code is inactive (see [Table 55-27](#)). Similarly, a Tx MB with a 1000b or 1001b code is also inactive (see [Table 55-28](#)).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also [FlexCAN memory partition for CAN FD](#).

### 55.3.1 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled. User and Supervisor modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Loop-Back mode:

The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station

will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- **CAN FD Active mode:**

In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD, Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

**Table 55-4. Differences between CAN classical and CAN FD**

| Feature                   | CAN classical | CAN FD |
|---------------------------|---------------|--------|
| Rx FIFO DMA               | Yes           | No     |
| Rx FIFO                   | Yes           | No     |
| Pretended network support | Yes           | No     |

For low-power operation, the FlexCAN module has:

- **Module Disable mode:**

This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM\_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See [Module Disable mode](#) for more information.

- **Stop mode:**

This low power mode is entered when Stop mode is requested at chip level and MCR[LPM\_ACK] is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See [Stop mode](#) for more information.

- **Pretended Network mode:**

This mode can be selected to operate together with Stop mode. Before entering in one of these low power modes you must assert MCR[PNET\_EN]. When in low power mode, CHI sub-block clocks are shut down and CAN\_PE sub-block is kept clocked, so that the Rx receive process is still active to filter incoming messages (see

[Receive process under Pretended Networking mode](#)) as defined by the configuration registers (see Pretended Networking Control 1 Register (CTRL1\_PN)). Upon detecting a wakeup event, a Wake Up interrupt is issued to the system.

### 55.3.1.1 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

#### CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

#### 55.3.1.1.1 Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode.

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ\_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ\_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ\_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

#### 55.3.1.1.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

It is not recommended to use Module Disable mode under Pretended Networking mode. Negate MCR[MDIS] and wait for MCR[LPMACK] to negate before setting MCR[PNET\_EN].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register, the Rx FIFO Global Mask register. The Rx FIFO Information register, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

#### 55.3.1.1.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets MCR[LPMACK], negates MCR[FRZACK], and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets MCR[NOTRDY] and MCR[LPMACK]
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates MCR[LPMACK]. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus.

#### 55.3.1.1.4 Pretended Networking mode

This is a special low-power mode used to receive wakeup messages with low power consumption. This mode can be selected to operate together with Stop mode. Before entering one of these low-power modes, MCR [PNET\_EN] must be asserted. After

entering the low-power mode, CHI subblock is shut down and CAN\_PE subblock is kept active, so that the Rx receive process is still active to filter incoming messages (see [Receive process under Pretended Networking mode](#)) as defined by the configuration registers (see [Pretended Networking Control 1 Register \(CTRL1\\_PN\)](#)). Upon detecting a wakeup event, a Wake Up interrupt is issued to the system.

To enter Pretended Networking mode, FlexCAN must be in normal mode (neither in Freeze nor in Disable mode). Under Pretended Networking mode, FlexCAN keeps itself synchronized with the CAN BUS in Stop mode. Then, when Stop mode is requested, FlexCAN performs the following steps:

- Waits to be in Idle state, or else waits for the third bit of Intermission, and then checks it to be recessive.
- Sets MCR[LPM\_ACK].
- Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

FlexCAN can exit Pretended Networking mode by the following ways:

- The CPU removes the Stop Mode request.
- FlexCAN will wait until Bus Idle or third bit of Intermission state to negate MCR[LPM\_ACK].

The above exit ways can be triggered either by the FlexCAN action upon detecting a wakeup event and issuing the respective interrupt, or by the CPU itself upon being waked up by another method. In consequence, FlexCAN will wait until the Bus Idle state or until the third bit of Intermission state to negate MCR[LPM\_ACK] and resume Normal mode. This procedure ensures that FlexCAN will be synchronized to the CAN bus after exiting Pretended Networking mode. The CPU must wait for MCR[LPM\_ACK] to be negated before performing any access to FlexCAN.

### NOTE

For more information about the difference between FD and non-FD regarding this feature, see [Table 55-4](#).

## 55.3.2 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001b) to the CODE field of the Control and Status word to request an abort of the transmission.

3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO\_EN]).
7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
  - a. Set ID type via MB\_CS[IDE].
  - b. Set Remote Transmission Request (if needed) via MB\_CS[RTR].
  - c. If MCR[FDEN] is enabled, also configure the MB\_CS[EDL] and MB\_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB\_CS[ESI] field, see [Table 55-9](#).<sup>1</sup>
  - d. Set Data Length Code in bytes via MB\_CS[DLC]. See [Table 55-29](#) for detailed information.
  - e. Activate the message buffer to transmit the CAN frame by setting MB\_CS[CODE] to Ch.

### NOTE

It is strongly recommended that all the fields in MB\_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB\_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant CCh pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

---

1. The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB\_CS[ESI] bit according to the error status of the node which sent the message.

The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 55-27](#) and [Table 55-28](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

### NOTE

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (1000b) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).

## 55.3.3 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

### 55.3.3.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

### 55.3.3.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

#### 55.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

**Table 55-5. Composition of the arbitration value when local priority is disabled**

| Format             | Mailbox arbitration value (32 bits) |             |             |                             |             |
|--------------------|-------------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | Standard ID (11 bits)               | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits)        | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

#### 55.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 55-6. Composition of the arbitration value when local priority is enabled**

| Format             | Mailbox arbitration value (35 bits) |                              |             |             |                             |             |
|--------------------|-------------------------------------|------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | PRI0 (3 bits)                       | Standard ID (11 bits)        | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | PRI0 (3 bits)                       | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

Because the PRI0 field is the most significant part of the arbitration value, mailboxes with low PRI0 values have higher priority than mailboxes with high PRI0 values regardless of the rest of their arbitration values.

Note that the PRI0 field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 55.3.3.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.
- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX\_ERR\_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time

to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during Bus Idle state. During this arbitration C/S write does not cause arbitration restart.

- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 55.3.4 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word into the mailbox.

3. Write the EMPTY code (0100b) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see [Move-in](#)) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 55-27](#) and [Table 55-28](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer to unlock the mailbox.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 55-27](#). If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

### CAUTION

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of IFLAG1[BUF5I] "Frames available in Rx FIFO"), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the data field.
4. Read the RXFIR register. (This step is optional, and is executed only if the IDHIT (Identifier Acceptance Filter Hit Indicator) is required in the application.)
5. Clear the Frames Available in Rx FIFO interrupt by writing one to IFLAG1[BUF5I] (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry).

When MCR[DMA] is asserted, upon receiving a frame in FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see [Rx FIFO under DMA operation](#)). The IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).
4. Read the last data bytes (read 8Ch address is mandatory).

### 55.3.5 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number message buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For Rx FIFO see [Rx FIFO](#).

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 55-7. Matching architecture**

| Structure         | SMB[RTR] | CTRL2[RRS] | CTRL2[EAC EN] | MB[IDE]          | MB[RTR]             | MB[ID <sup>1</sup> ] | MB[CODE]                 |
|-------------------|----------|------------|---------------|------------------|---------------------|----------------------|--------------------------|
| Mailbox           | 0        | —          | 0             | cmp <sup>2</sup> | no_cmp <sup>3</sup> | cmp_msk <sup>4</sup> | EMPTY or FULL or OVERRUN |
| Mailbox           | 0        | —          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 0          | —             | cmp              | no_cmp              | cmp                  | RANSWER                  |
| Mailbox           | 1        | 1          | 0             | cmp              | no_cmp              | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 1          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| FIFO <sup>5</sup> | —        | —          | —             | cmp_msk          | cmp_msk             | cmp_msk              | —                        |

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.

## Functional description

3. no\_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp\_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#)).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed.
- The Rx FIFO is not full.

The scan order for mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;
2. the last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and Rx FIFO with CTRL2[MRP].

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched in the scan for the Rx FIFO.
- If both conditions above are not satisfied and a non-free-to-receive matched mailbox is found, then the matching winner determination is conditioned by MCR[IRMQ]:
  - If MCR[IRMQ] is negated, the matching winner is the first matched mailbox.
  - If MCR[IRMQ] is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non-free-to-receive matched mailbox.

See the following table for a summary of matching possibilities.

**Table 55-8. Matching possibilities and resulting reception structures**

| RFEN                                                               | IRMQ | MRP            | Matched in MB     | Matched in FIFO       | Reception structure | Description                             |
|--------------------------------------------------------------------|------|----------------|-------------------|-----------------------|---------------------|-----------------------------------------|
| <b>No FIFO, only MB, match is always MB first</b>                  |      |                |                   |                       |                     |                                         |
| 0                                                                  | 0    | X <sup>1</sup> | None <sup>2</sup> | — <sup>3</sup>        | None                | Frame lost by no match                  |
| 0                                                                  | 0    | X              | Free <sup>4</sup> | —                     | First MB            |                                         |

## Functional description

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of [Rx Individual Mask Registers \(RXIMR0 - RXIMR31\)](#)). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXFGMASK, RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.

### 55.3.6 Receive process under Pretended Networking mode

Pretended Networking mode adds specific wakeup functionality in low power mode (Stop mode). When Pretended Networking mode (PN) is enabled by asserting MCR[PNET\_EN], FlexCAN continues processing Rx CAN messages under low power mode, and is able to detect specific wakeup messages by filtering them against ID and payload target values using preselected matching criteria. Wakeup functionality is not available for messages in CAN FD format. When in Pretended Networking mode, CAN FD format messages are ignored.

PN registers are located in the 0B00h–0B7Ch address range and can be written only in Freeze mode. These registers are used for writing PN configuration (both control and target values) prior to entering Pretended Networking mode, and for reading wakeup flags and the received message ID and data when returning back to normal mode after wakeup. The CPU must wait for MCR[LPMACK] to be negated before performing any access to FlexCAN PN registers.

PN control registers are described in Pretended Networking Control 1 Register (CTRL1\_PN) and Pretended Networking Control 2 Register (CTRL2\_PN). The control bit fields that configure the filtering criteria are:

- PLFS: payload filtering selection
- IDFS: ID filtering selection
- FCS: filtering combination selection

PN target values are:

- FLT\_IDE: IDE target value used to filter the incoming message by its format (standard or extended).
- FLT\_RTR: RTR target value used to filter the incoming message by its type (data or remote frame).
- FLT\_DLC\_HI and FLT\_DLC\_LO: target DLC range used to filter the size of payload part of an incoming message.
- FLT\_ID1: ID target value used to filter the incoming message ID (equal to, smaller than or equal, greater than or equal, or the lower limit value in an ID range).
- FLT\_ID2: ID target value used as the upper limit in an ID range.
- PL1: Payload target value used to filter the incoming message payload (equal to, smaller than or equal, greater than or equal, or the lower limit value in a payload range).
- PL2: Payload target value used as the upper limit in a payload range.

IDE, RTR, ID, and payload filters have their respective masks. These masks determine which bits are taken into account in equality comparisons ("1's" in certain mask positions) and which ones are don't care ("0's" in other mask positions). ID and payload masks are used only for exact ID and/or exact payload comparisons.

The ID of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact ID value by detecting the equality between the ID field of the incoming message and the content of target FLT\_ID1 register. The ID mask is used.
- A match with the maximum range of ID, that is, any message with ID value smaller than or equal to the content of target FLT\_ID1 register is accepted. The ID mask is not used.
- A match with the minimum range of ID, that is, any message with ID value greater than or equal to the content of target FLT\_ID1 register is accepted. The ID mask is not used.
- A match inside a range of IDs, that is, any message with an ID value that is greater than or equal to the content of target FLT\_ID1 register and smaller than or equal to the content of target FLT\_ID2\_IDMASK register is accepted. The ID mask is not used.

See CTRL1\_PN[IDFS] in [Pretended Networking Control 1 Register \(CTRL1\\_PN\)](#).

The above criteria for ID filtering must be coherent with FLT\_IDE and FLT\_RTR target values in FLT\_ID1 register. Only Rx frames that match the respective IDE and RTR bits to the contents of FLT\_IDE and FLT\_RTR bit fields will be compared. When a range of IDs is selected (CTRL1\_PN[IDFS] = 11), both FLT\_ID1 and FLT\_ID2 are referred to the same FLT\_IDE and FLT\_RTR bits in FLT\_ID1 register.

The ID mask is applied only to the exact ID comparison filtering option (CTRL1\_PN[IDFS] = 00) to determine which bits are taken into account in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range, and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are taken into account in comparison.

Similarly to the ID criteria, 64-bit data or payloads (PL) of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact payload value by detecting the equality between the payload field of the incoming message and the content of PL1 register. The payload mask is used.

- A match with the maximum range of payload, that is, any message with payload value smaller than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match with the minimum range of payload, that is, any message with payload value greater than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match inside a range of payloads, that is, any message with a payload value that is greater than or equal to the content of PL1 register and smaller than or equal to the content of PL2 register is accepted. The payload mask is not used.

See CTRL1\_PN[PLFS] in [Pretended Networking Control 1 Register \(CTRL1\\_PN\)](#).

The above criteria for payload filtering must be coherent with FLT\_DLC upper and lower limit values in FLT\_DLC register. The payload of an Rx incoming message is filtered in accordance with the selected criteria only if the DLC value of the Rx incoming message is inside a DLC range:

- Greater than or equal to the FLT\_DLC\_LO (lower limit)
- Lower than or equal to the FLT\_DLC\_HI (upper limit)

Conversely, a DLC value out of the specified range results in a mismatch. By making FLT\_DLC\_LO = FLT\_DLC\_HI, only payloads of the specified quantity of bytes will be filtered. DLC is not maskable.

When the inside range of payloads option is selected (CTRL1\_PN[PLFS] = 11), both PL1 and PL2 are considered with the 8-byte data length. All the data bytes excluded by the DLC of the received message are considered with value zero.

Payload mask is only used in the exact match option (CTRL1\_PN[PLFS] = 00) to select which bits or bytes in the 8-byte data field of both Rx incoming message and the contents of PL1 register are selected for matching. Mask length must be in accordance with the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When a remote frame is received by FlexCAN and CTRL1[FCS] is configured to select the payload comparison, the payload filtering is not considered and the comparison results in a mismatch.

Rx incoming messages can also be filtered based upon the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload for a predefined number of times. This number can be configured in the 1 to 255 range. See the Pretended Networking Control 1 Register (CTRL1\_PN).
- No message matching the filtering criteria for ID or payload up to a timeout trigger. That is, non-reception of a matching message for a defined quantity of time. See the Pretended Networking Control 2 Register (CTRL2\_PN).

FlexCAN can generate a wakeup timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag when the counting reaches the pre-defined timeout value, as specified in CTRL2\_PN[MATCHTO].

The above filtering criteria can be used together as follows:

- Message ID filtering only
- Message ID filtering and Payload filtering
- Message ID filtering only occurring N times
- Message ID filtering and Payload filtering occurring N times

The timeout counter runs concurrently with the reception filtering process. Both engines, timeout counter and message filtering, are independent. If an incoming message matches the selected filter criteria, the timeout counter keeps counting until the CPU wakes up. Conversely, if the timeout counter reaches the target value then the message filtering process continues to filter incoming messages until the CPU wakes up.

WU\_MTC[MOUNTER] will report the number of matched messages that occurred under Pretended Networking mode up to the moment the CPU wakes up.

Under Pretended Networking mode, the wakeup event that may occur will set the respective wakeup flag (see Pretended Networking Wake Up Match Register (WU\_MTC)):

- In case of a successful match in accordance with the selected filtering criteria, WU\_MTC[WUMF].
- In case of a timeout trigger, WU\_MTC[WTOF].

Any of these flags will generate interrupts to the CPU, provided the respective mask bits are enabled (CTRL1\_PN[WUMF\_MSK] or CTRL1\_PN[WTOF\_MSK]).

There are four Wake up Message Buffers (WMBs) used to store incoming messages in Pretended Networking mode. Up to four messages can be stored (see [Wake Up Message Buffer register for C/S \(WMB0\\_CS - WMB3\\_CS\)](#)).

When CTRL1\_PN[NMATCH] value is one, only one message is received if the filtering criteria are matched, and this message is stored in WMB0.

If NMATCH value is between two and four, WMB1, WMB2, and WMB3 are used to store the second, third, and fourth matching messages, respectively.

If NMATCH is greater than four, the last four matching messages are stored in the WMBs. The WMB index indicates the arrival order. The last message is stored in WMB3.

Only the valid data bytes of the incoming match message are stored in the data field of WMBs. The non-valid data bytes are read as zero. If DLC=0 and RTR=1, the data field is filled with zeroes. In any of the above cases, the wakeup interrupt is generated just when the filtering criteria is completed and CTRL1\_PN[WUMF\_MSK] is enabled.

When a non-match wakeup event occurs (timeout or external) and MCOUNTER register is equal to or greater than four, the message stored in WMB0 does not have valid content. WMB0 is used as a buffer for the current message in the CAN bus. Messages received during Pretended Networking mode don't have time stamps, and the respective field in the WMB structure must be ignored.

Under low power mode (Stop), all processes are shut down except for the PN functionality inside CAN\_PE sub-block, which is kept clocked by the oscillator clock (see [Clock domains and restrictions](#)). FlexCAN continues to receive Rx incoming messages but only compares them to the predefined target values and in accordance with the selected filtering criteria. The matching, arbitration, move-in and move-out processes, normally available in Normal mode, are not performed under Pretended Networking mode.

FlexCAN under Pretended Networking reacts to messages on the CAN bus in the same manner as in Normal mode (that is, it generates acknowledge bits, detect and count errors, etc.).

### 55.3.7 Move process

There are two types of move process: move-in and move-out.

#### 55.3.7.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN\_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:

- The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
- The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Rx FIFO.
2. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see [Mailbox inactivation](#)). In this case the mailbox may remain partially updated, thus incoherent. The exception is if the move-in destination is a Rx FIFO message buffer; then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

### 55.3.7.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see [Arbitration process](#)). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

## 55.3.8 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

### 55.3.8.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

### **55.3.8.2 Mailbox inactivation**

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see [Transmission abort mechanism](#)).

The inactivation automatically unlocks the mailbox (see [Mailbox lock mechanism](#)).

### NOTE

Message buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

## 55.3.8.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

### NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE (0b) or EMPTY<sup>1</sup> (0100b). Also, Tx MBs cannot be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see [Free Running Timer \(TIMER\)](#)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)), and it takes place only when the module returns to Normal or Freeze modes.

## 55.3.9 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

## CAUTION

Rx FIFO must not be enabled when CAN FD feature is enabled.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

**Note**

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the FIFO filter table is affected by RXFGMASK.

**NOTE**

For more information about the difference between FD and non-FD regarding this feature, see [Table 55-4](#).

**55.3.9.1 Rx FIFO under DMA operation**

The receive-only FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the FIFO output port at the 80h–8Ch address range.

**NOTE**

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear FIFO operation.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a message buffer). The DMA reading process must

end by reading address 8Ch, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

### NOTE

RXFIR register contents cannot be read after DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 080h (see [Rx FIFO structure](#)).

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

### NOTE

For more information about the difference between FD and non-FD regarding this feature, see [Table 55-4](#).

## 55.3.9.2 Clear FIFO operation

When MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

### CAUTION

Clear FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

## 55.3.10 CAN protocol related features

This section describes the CAN protocol related features.

### 55.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

### 55.3.10.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see [Remote frames](#)) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

**Figure 55-2. CAN message formats**

The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in [Message buffer structure](#)).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate

defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CBT register (also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the FDCBT register.

### **NOTE**

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

## CAN FD Frame

**Figure 55-3. Bit rate switching mechanism for CAN FD messages**

### NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN\_PE subblock. For example, with a CAN\_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.<sup>3</sup>

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

**Table 55-9. Written versus transmitted values of ESI field**

| FlexCAN fault confinement status at start of frame | ESI bit Of Tx MB | Transmitted ESI   |
|----------------------------------------------------|------------------|-------------------|
| Error active                                       | 0                | 0 (Error Active)  |
| Error passive                                      | 0                | 1 (Error Passive) |
| Error active                                       | 1                | 1 (Error Passive) |
| Error passive                                      | 1                | 1 (Error Passive) |

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC\_15, is used for all frames in Classical CAN format. The second, CRC\_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC\_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff

3. The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT\_FAST and TXERRCNT\_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1\_FAST, BITERR0\_FAST, CRCERR\_FAST, FRMERR\_FAST, and STFERR\_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT\_FAST and TXERRCNT\_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

### 55.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by `FDCTRL[TDCEN]` and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

### **NOTE**

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see [Protocol timing](#)), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in `FDCTRL[TDCOFF]`. `FDCTRL[TDCVAL]` stores the result of this calculation. The `TDCVAL` value saturates at its maximum value of 63 CANCLK when the delay measurement is too long.

**Figure 55-4. Transceiver loop delay measurement**

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRES DIV} + 1)$$

The following figure shows the SSP position when these settings are used.

**Figure 55-5. SSP position with optimal values**

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 T<sub>q</sub>. Beyond this limit, the FDCTRL[TDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

#### 55.3.10.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 1010b. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0100b, 0010b, or 0110b. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

**NOTE**

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

**55.3.10.5 Overload frames**

FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

**55.3.10.6 Time stamp**

The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field, providing network behavior with respect to time.

When CTRL2[TIMER\_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER\_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).

### 55.3.10.7 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. In order to guarantee reliable operation, the clock source should be selected when the module is in Disable mode (MCR[MDIS] is set).

#### NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

**Figure 55-6. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

#### NOTE

When the CAN FD feature is enabled, always set CBT[BTF] and configure the CAN bit timing variables in CBT. See [CAN Bit Timing Register \(CBT\)](#).

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine.

$$T_q = \frac{(\text{PRES DIV} + 1)}{f_{\text{CANCLK}}}$$

**Figure 55-7. Time quantum**

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * T_q$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

**Figure 55-8. CAN bit time and baud rate**

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 55-9](#), [Figure 55-10](#) and [Table 55-10](#)):

- **SYNC\_SEG:** This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- **Time Segment 1:** This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting CTRL1[PROPSEG] and CTRL1[PSEG1] so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CBT[BTF] is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- **Time Segment 2:** This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting CTRL1[PSEG2] (plus 1) to be 2 to 8 time quanta long. When CBT[BTF] is asserted, FlexCAN uses EPSEG2 fields of CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

### NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an

1. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

**Figure 55-9. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)**

**Figure 55-10. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)**

**Table 55-10. Time segment syntax**

| Syntax         | Description                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| SYNC_SEG       | System expects transitions to occur on the bus during this period.                                                                             |
| TSEG1          | Corresponds to the sum of PROPSEG and PSEG1.                                                                                                   |
| TSEG2          | Corresponds to the PSEG2 value.                                                                                                                |
| Transmit point | A node in transmit mode transfers a new value to the CAN bus at this point.                                                                    |
| Sample point   | A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample. |

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

**Table 55-11. Bosch CAN 2.0B standard compliant bit time segment settings**

| Time segment 1 | Time segment 2 | Re-synchronization jump width |
|----------------|----------------|-------------------------------|
| 5 .. 10        | 2              | 1 .. 2                        |
| 4 .. 11        | 3              | 1 .. 3                        |
| 5 .. 12        | 4              | 1 .. 4                        |
| 6 .. 13        | 5              | 1 .. 4                        |
| 7 .. 14        | 6              | 1 .. 4                        |
| 8 .. 15        | 7              | 1 .. 4                        |
| 9 .. 16        | 8              | 1 .. 4                        |

### Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRES DIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

**Figure 55-11. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0**

where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- $f_{\text{CANCLK}}$  is the Protocol Engine (PE) Clock (see [Figure 55-6](#)), in Hz.
- $f_{\text{SYS}}$  is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value in CTRL1[PSEG1] field.
- PSEG2 is the value in CTRL1[PSEG2] field.
- PROPSEG is the value in CTRL1[PROPSEG] field.
- PRES DIV is the value in CTRL1[PRES DIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) and also to the CAN FD Bit Timing register (FDCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

### 55.3.10.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 55-12. Matching and move-in time windows**

**Figure 55-13. Arbitration and move-out time windows**

**Figure 55-14. Arbitration at the end of bus off and move-out time windows**

#### NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

### 55.3.10.9 Tx arbitration start delay

CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see [Arbitration process](#)). If the arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

**Figure 55-15. Optimal Tx Arbitration start point**

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If T ASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if T ASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal T ASD value can be calculated as follows:

For CAN FD frames and  $(MAXMB + 1) \leq NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and  $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

**Figure 55-16. Optimal value for T ASD**

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left( \frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] * (EPRES DIV + 1)} \right)$$

$$BITRATE_F = \left( \frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] * (FPRES DIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

**Figure 55-17. Variables used in T ASD calculation**

- MAXMB is the value in CTRL1[MAXMB].
- NMB<sub>END</sub> is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- BITRATE<sub>N</sub> is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- BITRATE<sub>F</sub> is the CAN bit rate in bits per second calculated by the data CAN bit time variables.

## Functional description

- $CPCB_N$  is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$  is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- $CPCB$  is the number of peripheral clocks per CAN bit for non-FD frames.
- $f_{CANCLK}$  is the oscillator clock, in Hz.
- $f_{SYS}$  is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].
- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].

See also [Protocol timing](#) for more details.

The following tables give the T ASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 55-12. T ASD values:**

| Number of message buffers | T ASD value | Maximum bit rate in data phase (MBd) |
|---------------------------|-------------|--------------------------------------|
| 16                        | 24          | Invalid                              |
| 32                        | 24          | 8.0                                  |

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 55-13. T ASD values:**

| Number of message buffers | T ASD value | Maximum bit rate in data phase (MBd) |
|---------------------------|-------------|--------------------------------------|
| 16                        | 24          | Invalid                              |
| 32                        | 23          | 6.67                                 |

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 55-14. T ASD values:**

| Number of message buffers | T ASD value | Maximum bit rate in data phase (MBd) |
|---------------------------|-------------|--------------------------------------|
| 16                        | 24          | Invalid                              |
| 32                        | 23          | 4.0                                  |

## 55.3.11 Clocks

The following table describes the clock sources for FlexCAN. Please see chip clocking chapter for clock setting, configuration and gating information.

**Table 55-15. FlexCAN clocks**

| Clock name        | Description                        |
|-------------------|------------------------------------|
| ipg_clk           | Peripheral clock                   |
| ipg_clk_chi       | Control Host Interface (CHI) clock |
| ipg_clk_pe        | Protocol Engine (PE) clock         |
| ipg_clk_pe_nogate | Protocol Engine clock (no gating)  |
| ipg_clk_s         | Peripheral access clock            |

### 55.3.11.1 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When CTRL1[CLKSRC] is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

**NOTE**

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.

**Table 55-16. Minimum number of peripheral clocks per CAN bit for Classical CAN format**

| Number of mailboxes | Value of MCR[RFEN] | Minimum number of peripheral clocks per CAN bit |
|---------------------|--------------------|-------------------------------------------------|
| 16                  | 0                  | 16                                              |
| 32                  | 0                  | 16                                              |
| 16                  | 1                  | 16                                              |
| 32                  | 1                  | 17                                              |

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT). The time quantum (Tq) is defined in [Protocol timing](#). The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\begin{aligned} \text{NumClkNomBit} &= \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRES DIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4) \\ &= \frac{f_{\text{SYS}}}{\text{NomBitRate}} \end{aligned}$$

**Figure 55-18. Number of peripheral clocks per nominal CAN bit**

where PRES DIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRES DIV, EPSEG1, and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

**Table 55-17. Number of fast CAN bits in a CAN FD frame**

| Minimum number of data bytes | DLC field | NumOfFastBits |
|------------------------------|-----------|---------------|
| 0                            | 0h        | 21            |
| 1                            | 1h        | 29            |
| 2                            | 2h        | 37            |
| 3                            | 3h        | 45            |
| 4                            | 4h        | 53            |
| 5                            | 5h        | 61            |
| 6                            | 6h        | 69            |
| 7                            | 7h        | 77            |

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit<sub>A</sub>) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \times \text{MaxNumOfMb}) + 64 - (9 \times \text{NumClkNomBit})}{\text{NumOfFastBits}}$$

**Figure 55-19. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process**

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$\text{MinNumClkFastBit}_B = 3 \times \left( 1 + \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \right)$$

**Figure 55-20. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

Therefore, the minimum number of peripheral clocks per fast CAN bit ( $\text{MinNumClkFastBit}$ ) is determined by the larger of the two values calculated above.

$$\text{MinNumClkFastBit} = \text{Maximum} ( \text{MinNumClkFastBit}_A, \text{MinNumClkFastBit}_B )$$

**Figure 55-21. Minimum number of peripheral clocks per fast CAN bit**

Then, the maximum CAN bit rate in the data phase of CAN FD frames ( $\text{DataBitRateMAX}$ ) can be calculated as below.

$$\text{DataBitRate}_{\text{MAX}} = \frac{f_{\text{CANCLK}}}{\text{ROUNDUP} \left( \frac{\text{MinNumClkFastBit} \times f_{\text{CANCLK}}}{f_{\text{SYS}}} \right)}$$

**Figure 55-22. Maximum achievable baud rate for data phase**

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$\text{NumClkNomBit} = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

**Figure 55-23. Calculation example for number of peripheral clocks per nominal CAN bit**

2. The number of fast CAN bits ( $\text{NumOfFastBits}$ ) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit ( $\text{MinNumClkFastBit}$ ) can be calculated.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

**Figure 55-24. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process**

$$\text{MinNumClkFastBit}_B = 3 \times \left( 1 + \frac{50}{40} \right) = 6.75$$

**Figure 55-25. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

$$\text{MinNumClkFastBit} = \text{Maximum}(5.06, 6.75) = 6.75$$

**Figure 55-26. Calculation example for number of peripheral clocks per fast CAN bit**  
4. The maximum CAN bit rate in the data phase can finally be found.

$$\text{DataBitRate}_{\text{MAX}} = \frac{40 \times 10^6}{\text{ROUNDUP}\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667 \text{ Mbps}$$

**Figure 55-27. Calculation example for maximum achievable baud rate**

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

**Table 55-18. Maximum CAN bit rate in data phase on CAN FD frames**

| Peripheral clock frequency (MHz) | Payload size | Number of available mailboxes | Maximum data rate (Mbps) |
|----------------------------------|--------------|-------------------------------|--------------------------|
| 40                               | 8            | 94                            | 6.667                    |
| 40                               | 8            | 114                           | 5.0                      |
| 40                               | 12           | 117                           | 6.667                    |
| 40                               | 12           | 128                           | 5.714                    |
| 50                               | 12 to 64     | 128                           | 6.667                    |
| 60                               | 8            | 126                           | 8.0                      |
| 60                               | 12           | 128                           | 8.0                      |
| 67                               | 6            | 128                           | 8.0                      |
| 80                               | 3            | 128                           | 8.0                      |
| 100                              | 0            | 128                           | 8.0                      |

### 55.3.12 Reset

You can reset FlexCAN in the following ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTTRST], which resets some of the memory-mapped registers synchronously. See [Table 55-21](#) to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC] description in [Control 1 Register \(CTRL1\)](#)). After the clock source is selected and the module is enabled (MCR[MDIS] bit negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

### 55.3.13 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Wake Up Match, Wake Up Timeout, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled ( $\text{MCR}[\text{RFEN}] = 1$ ) and DMA is disabled ( $\text{MCR}[\text{DMA}] = 0$ ), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of [Interrupt Flags 1 Register \(IFLAG1\)](#) for more information.

If both Rx FIFO and DMA are enabled ( $\text{MCR}[\text{RFEN}]$  and  $\text{MCR}[\text{DMA}] = 1$ ) the FlexCAN does not generate any FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

### CAUTION

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register.

The interrupt sources for Pretended Networking (Wake up by Match Flag and Wake up by Timeout Flag) can be read in the WU\_MTC register and the respective interrupt mask bits are located in CTRL1\_PN register.

## 55.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in [Table 55-21](#) in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  - a. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  - b. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0h, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0080h, and the space 0080h–008Fh is used by the one MB. The memory space 0090h–017Fh is available. The space 0180h–087Fh is reserved. The space 0880h–0883h is used by the one individual mask and the available memory in the mask registers space would be 0884h–08BFh. From 08C0h–09DFh there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.
  - c. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

**Table 55-19. Access permissions**

| Supervisor access                  | 0          |            |            |           | 1          |            |            |
|------------------------------------|------------|------------|------------|-----------|------------|------------|------------|
| Supervisor mode -<br>MCR[SUPV] = 1 | 0          |            |            | 1         | any        |            |            |
| Modes of operation                 | Normal     | Freeze     | Low power  | *         | Normal     | Freeze     | Low power  |
| MCR                                | bus error  | bus error  | bus error  | bus error | read/write | read/write | read/write |
| CTRL1                              | read/write | read write | read/write | bus error | read/write | read/write | read/write |

*Table continues on the next page...*

| Reserved space (empty) <sup>1</sup> | bus error                     | bus error                     | bus error                     | bus error | bus error                     | bus error                     | bus error                     |

1. Access in low power is only possible if RAM\_clk and ipg\_clk are enabled.
2. If MCR[RFEN] = 1, see FIFO access rules below.
3. Write operation has no effect.

## 55.4 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 55-20. FlexCAN signal descriptions**

| Signal | Description      | I/O    |
|--------|------------------|--------|
| CAN Rx | CAN receive pin  | Input  |
| CAN Tx | CAN transmit pin | Output |

### 55.4.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 55.4.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 55.5 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 55.5.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of [Table 55-21](#).

#### NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

**Table 55-21. Register access and reset information**

| Register                            | Access type | Affected by hard reset | Affected by soft reset |
|-------------------------------------|-------------|------------------------|------------------------|
| Module Configuration Register (MCR) | S           | Yes                    | Yes                    |
| Control 1 Register (CTRL1)          | S/U         | Yes                    | No                     |
| Free Running Timer Register (TIMER) | S/U         | Yes                    | Yes                    |

*Table continues on the next page...*

**Table 55-21. Register access and reset information (continued)**

| Register                                                                                         | Access type | Affected by hard reset | Affected by soft reset |
|--------------------------------------------------------------------------------------------------|-------------|------------------------|------------------------|
| Rx Mailboxes Global Mask Register (RXMGMASK)                                                     | S/U         | No                     | No                     |
| Rx Buffer 14 Mask Register (RX14MASK)                                                            | S/U         | No                     | No                     |
| Rx Buffer 15 Mask Register (RX15MASK)                                                            | S/U         | No                     | No                     |
| Error Counter Register (ECR)                                                                     | S/U         | Yes                    | Yes                    |
| Error and Status 1 Register (ESR1)                                                               | S/U         | Yes                    | Yes                    |
| Interrupt Masks 1 Register (IMASK1)                                                              | S/U         | Yes                    | Yes                    |
| Interrupt Flags 1 Register (IFLAG1)                                                              | S/U         | Yes                    | Yes                    |
| Control 2 Register (CTRL2)                                                                       | S/U         | Yes                    | No                     |

| Pretended Networking Payload High Filter 2 Register / Payload High Mask Register (PL2_PLMASK_HI) | S/U         | Yes                    | Yes                    |
| Pretended Networking Wake Up Message Buffer 0 Register (WMB0)                                    | S/U         | Yes                    | No                     |
| Pretended Networking Wake Up Message Buffer 1 Register (WMB1)                                    | S/U         | Yes                    | No                     |
| Pretended Networking Wake Up Message Buffer 2 Register (WMB2)                                    | S/U         | Yes                    | No                     |
| Pretended Networking Wake Up Message Buffer 3 Register (WMB3)                                    | S/U         | Yes                    | No                     |
| CAN FD Control Register (FDCTRL)                                                                 | S/U         | Yes                    | No                     |
| CAN FD Bit Timing Register (FDCBT)                                                               | S/U         | Yes                    | No                     |
| CAN FD CRC Register (FDCRC)                                                                      | S/U         | Yes                    | Yes                    |

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

## 55.5.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–27Fh allocates the thirty-two 128-bit message buffers (MBs).

The memory maps for the message buffers are in [FlexCAN message buffer memory map](#).

### 55.5.2.1 CAN memory map

FlexCAN0 base address: 4002\_4000h

FlexCAN1 base address: 4002\_5000h

FlexCAN2 base address: 4002\_B000h

| Offset      | Register                                                             | Width<br>(In bits) | Access | Reset value                 |

## 55.5.2.2 Module Configuration Register (MCR)

### 55.5.2.2.1 Offset

| Register | Offset |
|----------|--------|
| MCR      | 0h     |

### 55.5.2.2.2 Function

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

### 55.5.2.2.3 Diagram

### 55.5.2.2.4 Fields

| Field      | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>MDIS | Module Disable<br>This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset.<br>0b - Enable the FlexCAN module.<br>1b - Disable the FlexCAN module.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 30<br>FRZ  | Freeze Enable<br>The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.<br>0b - Not enabled to enter Freeze mode.<br>1b - Enabled to enter Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 29<br>RFEN | Rx FIFO Enable<br>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (80h–DCh) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 55-16</a> . This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.<br><b>NOTE:</b> This bit cannot be set when CAN FD operation is enabled (see FDEN bit).<br>0b - Rx FIFO not enabled.<br>1b - Rx FIFO enabled. |
| 28         | Halt FlexCAN                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Field        | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HALT         | Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the message buffers and the Control registers CTRL1 and CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered when FlexCAN is in a low power mode.<br>0b - No Freeze mode request.<br>1b - Enters Freeze mode if the FRZ bit is asserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 27<br>NOTRDY | FlexCAN Not Ready<br>This read-only bit indicates that FlexCAN is either in Disable mode, Stop mode or Freeze mode. It is negated when FlexCAN has exited these modes. This bit is not affected by soft reset.<br>0b - FlexCAN module is either in Normal mode, Listen-Only mode, or Loop-Back mode.<br>1b - FlexCAN module is either in Disable mode, Stop mode, or Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 26<br>—      | Reserved<br>When writing to this field, always write the reset value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 25<br>SOFRST | Soft Reset<br>When SOFRST is asserted, FlexCAN resets its internal state machines and some of the memory-mapped registers.<br><br>SOFRST can be asserted directly by the CPU when it writes to the MCR register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFRST bit remains asserted when reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.<br><br>Soft reset cannot be applied when clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset.<br><br>0b - No reset request.<br>1b - Resets the registers affected by soft reset.                                                                                                              |
| 24<br>FRZACK | Freeze Mode Acknowledge<br>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See <a href="#">Freeze mode</a> . This bit is not affected by soft reset.<br><br><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the Freeze mode request by the CPU, and negated within 2 CAN bits after the Freeze mode request removal (see <a href="#">Protocol timing</a> ).<br>0b - FlexCAN not in Freeze mode, prescaler running.<br>1b - FlexCAN in Freeze mode, prescaler stopped. |
| 23<br>SUPV   | Supervisor Mode<br>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of <a href="#">Table 55-21</a> . Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br>0b - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses.<br>1b - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.                                                                                                                                                                                                                                                                                    |
| 22<br>—      | Reserved<br>When writing to this field, always write the reset value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 21<br>WRNEN  | Warning Interrupt Enable<br>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.<br>0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.<br>1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.                                                                                                                                                                                                                                                                                                                                                                                       |
| 20<br>LPMACK  | Low-Power Mode Acknowledge<br><br>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset.<br><br><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see <a href="#">Protocol timing</a> ). When FlexCAN is in Pretended Networking mode LPMACK will be negated within 180 CAN bits after the low-power mode request removal.<br>0b - FlexCAN is not in a low-power mode.<br>1b - FlexCAN is in a low-power mode. |
| 19<br>—       | Reserved<br><br>When writing to this field, always write the reset value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 18<br>—       | Reserved<br><br>When writing to this field, always write the reset value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 17<br>SRXDIS  | Self Reception Disable<br><br>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br>0b - Self-reception enabled.<br>1b - Self-reception disabled.                                                                                                                                                                                                                                                                         |
| 16<br>IRMQ    | Individual Rx Masking And Queue Enable<br><br>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.<br>0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.<br>1b - Individual Rx masking and queue feature are enabled.                                                                                                                                                                                                                                                             |
| 15<br>DMA     | DMA Enable<br><br>DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, so consequently MCR[RFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes.<br><br>0b - DMA feature for RX FIFO disabled.<br>1b - DMA feature for RX FIFO enabled.                                                                                                                                                                                                                                                                                                                                                                |
| 14<br>PNET_EN | Pretended Networking Enable<br><br>This bit enables the Pretended Networking functionality. When in Stop mode, PE sub-block is kept operational, making it able to process Rx message filtering as defined by the Pretended Networking configuration registers. See <a href="#">Receive process under Pretended Networking mode</a> . This bit can be written in Freeze mode only.<br><br><b>NOTE:</b> This field is not supported in every instance. The following table includes only supported registers.                                                                                                                                                                                                                                                                                                                |

| 13<br>LPRIEN | <b>Local Priority Enable</b><br>This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br>0b - Local Priority disabled.<br>1b - Local Priority enabled.                                                                                              |                    |                        |
| 12<br>AEN    | <b>Abort Enable</b><br>When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see <a href="#">Transmission abort mechanism</a> ) must be used for updating mailboxes configured for transmission.<br><b>CAUTION:</b> Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted.<br>0b - Abort disabled.<br>1b - Abort enabled.                  |                    |                        |
| 11<br>FDEN   | <b>CAN FD operation enable</b><br>This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only.<br><b>NOTE:</b> FlexCAN is able to transmit FD frame format according to ISO 11898-1.<br><b>NOTE:</b> The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted.<br>0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format.<br>1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats.                                                                                                                                                                 |                    |                        |

| 6-0<br>MAXMB | <p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in <a href="#">FlexCAN memory partition for CAN FD</a>.</p> <p>Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 55-16</a>.</p> |

#### 55.5.2.3.2 Function

This Register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRES DIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRES DIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

#### NOTE

When the CAN FD feature is enabled, do not use the PRES DIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRES DIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

The contents of this register are not affected by soft reset.

**55.5.2.3.4 Fields**

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>PRESDIV | <p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Sclock frequency = PE clock frequency / (PRESDIV + 1).</p> |
| 23-22<br>RJW     | <p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Resync Jump Width = RJW + 1.</p>                                                                                                                                                                                                                |
| 21-19<br>PSEG1   | <p>Phase Segment 1</p> <p>This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See <a href="#">Protocol timing</a> for more information. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.</p>                                                                                                                                                                                                                                                                                       |
| 18-16<br>PSEG2   | Phase Segment 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 13<br>CLKSRC  | <p>CAN Engine Clock Source</p> <p>This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the serial clock (Sclck). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See <a href="#">Protocol timing</a>.</p> <p><b>NOTE:</b> The user must ensure the protocol engine clock tolerance according to the CAN Protocol standard (ISO 11898-1).</p> <p><b>NOTE:</b> See the clock distribution chapter (module clocks table) to identify the proper clock source.</p> <p>0b - The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock.<br/>1b - The CAN engine clock source is the peripheral clock.</p>                                                                                                                                                                                                                            |
| 12<br>LPB     | <p>Loop Back Mode</p> <p>This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node.</p> <p>In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, MCR[SRXDIS] cannot be asserted because this will impede the self-reception of a transmitted message.</p> <p><b>NOTE:</b> FDCTRL[TDCEN] must be disabled when LPB is asserted.</p> <p>0b - Loop Back disabled.<br/>1b - Loop Back enabled.</p> |
| 11<br>TWRNMSK | <p>Tx Warning Interrupt Mask</p> <p>This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted.</p> <p>0b - Tx Warning interrupt disabled.<br/>1b - Tx Warning interrupt enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 7<br>SMP     | <p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]). This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1).</p> <p>0b - Just one sample is used to determine the bit value.<br/>1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 6<br>BOFFREC | <p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p><b>NOTE:</b> See Bus off in the CAN Protocol standard (ISO 11898-1) for details.<br/>0b - Automatic recovering from Bus Off state enabled.<br/>1b - Automatic recovering from Bus Off state disabled.</p> |
| 5<br>TSYN    | <p>Timer Sync</p> <p>This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message, that is, global network time. If MCR[RFEN] is set (Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0b - Timer sync feature disabled<br/>1b - Timer sync feature enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 4<br>LBUF    | <p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for message buffer transmission. When asserted, MCR[LPRI0EN] does not affect the priority arbitration. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.</p> <p>0b - Buffer with highest priority is transmitted first.<br/>1b - Lowest number buffer is transmitted first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3<br>LOM     | <p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in the ECR register are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it was trying to acknowledge the message.</p> <p>Listen-Only mode is acknowledged by the state of ESR1[FLTCONF] indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 55.5.2.4 Free Running Timer (TIMER)

### 55.5.2.4.1 Offset

| Register | Offset |
|----------|--------|
| TIMER    | 8h     |

### 55.5.2.4.2 Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0h after Reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER\_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER\_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, Pretended Networking, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see [Mailbox lock mechanism](#)).

## 55.5.2.5 Rx Mailboxes Global Mask Register (RXMGMASK)

### 55.5.2.5.1 Offset

| Register | Offset |
|----------|--------|
| RXMGMASK | 10h    |

### 55.5.2.5.2 Function

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).
2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

## 55.5.2.6 Rx 14 Mask Register (RX14MASK)

### 55.5.2.6.1 Offset

| Register | Offset |
|----------|--------|
| RX14MASK | 14h    |

### 55.5.2.6.2 Function

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.

This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

### 55.5.2.8 Error Counter (ECR)

#### 55.5.2.8.1 Offset

| Register | Offset |
|----------|--------|
| ECR      | 1Ch    |

#### 55.5.2.8.2 Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT\_FAST field)
- Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT\_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT\_FAST and RXERRCNT\_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT\_FAST and RXERRCNT\_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCNF] is updated to reflect Error Passive state.
- If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCNF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCNF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCNF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT\_FAST counter is frozen during Bus Off.
- If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.
- TXERRCNT\_FAST and RXERRCNT\_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.
- When FlexCAN is in Pretended Networking mode, RXERRCNT and RXERRCNT\_FAST keep counting errors and error flags are stored. TXERRCNT and TXERRCNT\_FAST preserve their values and do not change, because no transmission occurs under Pretended Networking mode. Error counters and error flags that changed values when in Pretended Networking mode are updated in ECR and ESR1 when FlexCAN returns to Normal mode. The FAST error flags in ESR1 register will not be set if FlexCAN is in Pretended Networking mode.

**NOTE**

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

| Register | Offset |
|----------|--------|
| ESR1     | 20h    |

### 55.5.2.9.2 Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

#### NOTE

Reading Host can clear these field.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR\_FAST
  - BIT0ERR\_FAST
  - CRCERR\_FAST
  - FRMERR\_FAST
  - STFERR\_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt bits:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT\_FAST

- TWRNINT
- RWRNINT

It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR\_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT\_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR\_OVR bit is set to indicate that errors from different frames have accumulated.

**Table 55-22. Can bus status**

| SYNCH | IDLE | TX | RX | FlexCAN state               |
|-------|------|----|----|-----------------------------|
| 0     | 0    | 0  | 0  | Not synchronized to CAN bus |
| 1     | 1    | x  | x  | Idle                        |
| 1     | 0    | 1  | 0  | Transmitting                |
| 1     | 0    | 0  | 1  | Receiving                   |

### NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

| 25-22<br>—        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 21<br>ERROVR      | <p>Error Overrun</p> <p>This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1.</p> <p>0b - Overrun has not occurred.<br/>1b - Overrun has occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                |
| 20<br>ERRINT_FAST | <p>Error interrupt for errors detected in Data Phase of CAN FD frames with BRS bit set</p> <p>This bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If the corresponding mask bit CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence.<br/>1b - Indicates setting of any error bit detected in the data phase of CAN FD frames with the BRS bit set.</p>          |
| 19<br>BOFFDONEINT | <p>Bus Off Done Interrupt</p> <p>This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0b - No such occurrence.<br/>1b - FlexCAN module has completed Bus Off process.</p>                                                                                                                                      |
| 18<br>SYNCH       | <p>CAN Synchronization Status</p> <p>This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall ESR1 register description.</p> <p>0b - FlexCAN is not synchronized to the CAN bus.<br/>1b - FlexCAN is synchronized to the CAN bus.</p>                                                                                                                                                                                                                                          |
| 17<br>TWRNINT     | <p>Tx Warning Interrupt Flag</p> <p>If MCR[WRNEN] is asserted, TWRNINT is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When MCR[WRNEN] is negated, this flag is masked. CPU must clear this flag before disabling MCR[WRNEN]. Otherwise it will be set when MCR[WRNEN] is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.</p> |

|               | <p>When FlexCAN returns to Normal mode from Pretended Network mode (see <a href="#">Receive process under Pretended Networking mode</a>), this bit is not updated.</p> <p>0b - No such occurrence.<br/>1b - The Tx error counter transitioned from less than 96 to greater than or equal to 96.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 16<br>RWRNINT | <p>Rx Warning Interrupt Flag</p> <p>If MCR[WRNEN] is asserted, RWRNINT is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode.</p> <p>When FlexCAN returns to Normal mode from Pretended Network mode (see <a href="#">Receive process under Pretended Networking mode</a>), this bit is updated to reflect the Rx error counter state.</p> <p>0b - No such occurrence.<br/>1b - The Rx error counter transitioned from less than 96 to greater than or equal to 96.</p> |
| 15<br>BIT1ERR | <p>Bit1 Error</p> <p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.</p> <p>This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode.</p> <p><b>NOTE:</b> This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence.<br/>1b - At least one bit sent as recessive is received as dominant.</p>                                                                                                                                                                                                                                                   |

## Memory map/register definition

| Field          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | 1b - A CRC error occurred since last read of this register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 11<br>FRMERR   | <p>Form Error</p> <p>This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence.<br/>1b - A Form Error occurred since last read of this register.</p>                                                                                                            |
| 10<br>STFERR   | <p>Stuffing Error</p> <p>This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node.</p> <p>This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence.<br/>1b - A stuffing error occurred since last read of this register.</p>                                                                                                                                                            |
| 9<br>TXWRN     | <p>TX Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence.<br/>1b - TXERRCNT is greater than or equal to 96.</p>                                                                                                                                                                                                                                    |
| 8<br>RXWRN     | <p>Rx Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode.</p> <p>Additionally, it is updated when FlexCAN returns to Normal mode from Pretended Networking mode.</p> <p>After a read operation, the field's value clears to 0.</p> <p>0b - No such occurrence.<br/>1b - RXERRCNT is greater than or equal to 96.</p>                                                                                                                                |
| 7<br>IDLE      | <p>IDLE</p> <p>This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description.</p> <p>0b - No such occurrence.<br/>1b - CAN bus is now IDLE.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6<br>TX        | <p>FlexCAN In Transmission</p> <p>This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description.</p> <p>0b - FlexCAN is not transmitting a message.<br/>1b - FlexCAN is transmitting a message.</p>                                                                                                                                                                                                                                                                                                                                                            |
| 5-4<br>FLTCONF | <p>Fault Confinement State</p> <p>This 2-bit field indicates the confinement state of the FlexCAN module.</p> <p>If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again.</p> <p>This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive.</p> |

## 55.5.2.10 Interrupt Masks 1 Register (IMASK1)

### 55.5.2.10.1 Offset

| Register | Offset |
|----------|--------|
| IMASK1   | 28h    |

### 55.5.2.10.2 Function

This register allows any number of a range of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

## 55.5.2.11 Interrupt Flags 1 Register (IFLAG1)

### 55.5.2.11.1 Offset

| Register | Offset |
|----------|--------|
| IFLAG1   | 30h    |

### 55.5.2.11.2 Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO, BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see [Rx FIFO](#). Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When MCR[RFEN] is negated, the FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Rx FIFO filters beyond MB7. For example, when RFFN is 8h, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When MCR[DMA] is negated, the FIFO must be empty. FIFO must be disabled when MCR[FDEN] is enabled.

Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

### 55.5.2.11.3 Diagram

## 55.5.2.11.4 Fields

| Field             | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8<br>BUF31TO8I | <p>Buffer MBi Interrupt</p> <p>Each bit flags the corresponding FlexCAN message buffer interrupt for MB31 to MB8.</p> <p>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception.<br/>1b - The corresponding buffer has successfully completed transmission or reception.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7<br>BUF7I        | <p>Buffer MB7 Interrupt Or Rx FIFO Overflow</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>The BUF7I flag represents Rx FIFO overflow when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a mailbox.</p> <p>0b - No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1<br/>1b - MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1</p>                                                                                                                                                                                                                              |
| 6<br>BUF6I        | <p>Buffer MB6 Interrupt Or Rx FIFO Warning</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>The BUF6I flag represents Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than four.</p> <p>0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1<br/>1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1</p> |
| 5<br>BUF5I        | <p>Buffer MB5 Interrupt Or Frames available in Rx FIFO</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB5.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I.</p> <p>0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1<br/>1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.</p>                                                          |
| 4-1<br>BUF4TO1I   | <p>Buffer MBi Interrupt Or Reserved</p> <p>When MCR[RFEN] is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.</p> <p><b>NOTE:</b> These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</p> <p>The BUF4TO1I flags are reserved when MCR[RFEN] is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 0<br>BUF0I | Buffer MB0 Interrupt Or Clear FIFO bit<br><br>When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGS. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions.<br><br>0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.<br>1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0. |

## 55.5.2.12 Control 2 Register (CTRL2)

### 55.5.2.12.1 Offset

| Register | Offset |
|----------|--------|
| CTRL2    | 34h    |

### 55.5.2.12.2 Function

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

**Table 55-23. Rx FIFO filter: possible structures**

| RFFN[3:0] | Number of Rx FIFO filter elements | Message buffers occupied by Rx FIFO and ID filter table | Remaining available mailboxes | Rx FIFO ID filter table elements affected by Rx individual masks | Rx FIFO ID filter table elements affected by Rx FIFO global mask |
|-----------|-----------------------------------|---------------------------------------------------------|-------------------------------|------------------------------------------------------------------|------------------------------------------------------------------|

|          | <p>When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition.</p> <p>This field is writable only in Freeze mode.</p> <p><b>NOTE:</b> See Bus Integration state in the CAN Protocol standard (ISO 11898-1) for details.<br/> 0b - Edge filter is enabled<br/> 1b - Edge filter is disabled</p> |

| 22-16<br>LPTM | <p>Lowest Priority Tx Mailbox</p> <p>If ESR2[VPS] is asserted, this field indicates the lowest number inactive mailbox (see the ESR2[IMB] bit description). If there is no inactive mailbox then the mailbox indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] is negated, then the mailbox indicated is the one that has the greatest arbitration value (see <a href="#">Highest-priority mailbox first</a>). If CTRL1[LBUF] is asserted then the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its mailbox number.</p>                                                                                                                                                                                                                                                                                                 |
| 15<br>—       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 14<br>VPS     | <p>Valid Priority Status</p> <p>This bit indicates whether ESR2[IMB] and ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive mailbox and only one Tx mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any mailbox.</p> <p><b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of an MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.</p> <p>0b - Contents of IMB and LPTM are invalid.<br/>1b - Contents of IMB and LPTM are valid.</p> |
| 13<br>IMB     | <p>Inactive Mailbox</p> <p>If ESR2[VPS] is asserted, this bit indicates whether there is any inactive mailbox (CODE field is either 1000b or 0b). This bit is asserted in the following cases:</p> <ul style="list-style-type: none"> <li>• During arbitration, if an ESR2[LPTM] is found and it is inactive.</li> <li>• If ESR2[IMB] is not asserted and a frame is transmitted successfully.</li> </ul> <p>This bit is always cleared in start of arbitration (see <a href="#">Arbitration process</a>).</p> <p><b>NOTE:</b> ESR2[LPTM] mechanism has the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM].</p> <p>0b - If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive mailbox.<br/>1b - If ESR2[VPS] is asserted, there is at least one inactive mailbox. LPTM content is the number of the first one.</p>                              |

### 55.5.2.14 CRC Register (CRCR)

### 55.5.2.14.1 Offset

| Register | Offset |
|----------|--------|
| CRCR     | 44h    |

### 55.5.2.14.2 Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

#### NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

| TXCRC | This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in FDCRC register. |

## 55.5.2.15 Rx FIFO Global Mask Register (RXFGMASK)

### 55.5.2.15.1 Offset

| Register | Offset |
|----------|--------|
| RXFGMASK | 48h    |

### 55.5.2.15.2 Function

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

**Table 55-24. Correspondence of Rx FIFO global mask bits to IDF fields**

| Rx FIFO ID filter table elements format (MCR[IDAM]) | Identifier acceptance filter fields |                     |           |                          |                                                      | Reserved |
|-----------------------------------------------------|-------------------------------------|---------------------|-----------|--------------------------|------------------------------------------------------|----------|
|                                                     | RTR                                 | IDE                 | RXIDA     | RXIDB <sup>1</sup>       | RXIDC <sup>2</sup>                                   |          |
| A                                                   | FGM[31]                             | FGM[30]             | FGM[29:1] | —                        | —                                                    | FGM[0]   |
| B                                                   | FGM[31],<br>FGM[15]                 | FGM[30],<br>FGM[14] | —         | FGM[29:16],<br>FGM[13:0] | FGM[31:24],<br>FGM[23:16],<br>FGM[15:8],<br>FGM[7:0] | —        |
| C                                                   | —                                   | —                   |           | —                        |                                                      |          |

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.

## 55.5.2.16 Rx FIFO Information Register (RXFIR)

### 55.5.2.16.1 Offset

| Register | Offset |
|----------|--------|
| RXFIR    | 4Ch    |

### 55.5.2.16.2 Function

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO. Also, its output is updated whenever the output of the Rx FIFO is updated with the next message. See [Rx FIFO](#) for instructions on reading this register.

| 31-9<br>—    | Reserved                                                                                                                                                                                                                                                                                                                                                                        |
| 8-0<br>IDHIT | Identifier Acceptance Filter Hit Indicator<br>This field indicates which Identifier Acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5!] is asserted. |

## 55.5.2.17 CAN Bit Timing Register (CBT)

### 55.5.2.17.1 Offset

| Register | Offset |
|----------|--------|
| CBT      | 50h    |

### 55.5.2.17.2 Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

**NOTE**

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

**NOTE**

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

## 55.5.2.18 Rx Individual Mask Registers (RXIMR0 - RXIMR31)

### 55.5.2.18.1 Offset

For n = 0 to 31:

| Register | Offset          |
|----------|-----------------|
| RXIMRn   | 880h + (n × 4h) |

### 55.5.2.18.2 Function

The RX Individual Mask registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see [Rx FIFO](#)).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See [Bus interface](#) for more information.

## 55.5.2.19 Pretended Networking Control 1 Register (CTRL1\_PN)

### 55.5.2.19.1 Offset

| Register | Offset |
|----------|--------|
| CTRL1_PN | B00h   |

### 55.5.2.19.2 Function

This register contains control bits for Pretended Networking mode filtering selection. Configure this register with the filter criteria to be used to receive wakeup messages. It can be written in Freeze mode only, except WTOF\_MSK and WUMF\_MSK bits.

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | CTRL1_PN           | —                      |
| FlexCAN1 | —                  | CTRL1_PN               |
| FlexCAN2 | —                  | CTRL1_PN               |

## 55.5.2.20 Pretended Networking Control 2 Register (CTRL2\_PN)

### 55.5.2.20.1 Offset

| Register | Offset |
|----------|--------|
| CTRL2_PN | B04h   |

### 55.5.2.20.2 Function

This register contains configuration bits for the timeout value under Pretended Networking mode. It can be written in Freeze mode only.

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | CTRL2_PN           | —                      |
| FlexCAN1 | —                  | CTRL2_PN               |

| —               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15-0<br>MATCHTO | <p>Timeout for No Message Matching the Filtering Criteria</p> <p>This 16-bit field defines a timeout value that generates a wakeup event if MCR[PNET_EN] is asserted. If the timeout counter reaches the target value, when FlexCAN is under Pretended Networking mode, then a wakeup event is generated. The timeout limit can be configured from 1 to 65535 to control an internal 16-bit up-count timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, which period is 64 times the CAN Bit Time unit. When MATCHTO is configured with 0000h the timeout is disabled.</p> |

## 55.5.2.21 Pretended Networking Wake Up Match Register (WU\_MTC)

### 55.5.2.21.1 Offset

| Register | Offset |
|----------|--------|
| WU_MTC   | B08h   |

### 55.5.2.21.2 Function

This read-only register contains wakeup information related to the matching processes performed while FlexCAN receives frames under Pretended Networking mode.

### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | WU_MTC             | —                      |
| FlexCAN1 | —                  | WU_MTC                 |
| FlexCAN2 | —                  | WU_MTC                 |

## 55.5.2.21.3 Diagram

## 55.5.2.21.4 Fields

| Field            | Function                                                                                                                                                                                                                                                                                                                                    |

| 16<br>WUMF       | Wake Up by Match Flag Bit<br>This bit identifies whether the FlexCAN has detected a matching Rx incoming message, which passed the filtering criteria specified in CTRL1_PN register. This flag generates a wakeup event if CTRL1_PN[WUMF_MSK] is enabled.<br>0b - No wakeup by match event detected<br>1b - Wakeup by match event detected |
| 15-8<br>MCOUNTER | Number of Matches when in Pretended Networking<br>This 8-bit field reports the number of times a given message has matched the predefined filtering criteria for ID and/or PL before a wakeup event. This register is reset by FlexCAN when it enters in Pretended Networking mode, and is not affected by soft reset.                      |
| 7-0<br>—         | Reserved                                                                                                                                                                                                                                                                                                                                    |

## 55.5.2.22 Pretended Networking ID Filter 1 Register (FLT\_ID1)

### 55.5.2.22.1 Offset

| Register | Offset |
|----------|--------|
| FLT_ID1  | B0Ch   |

### 55.5.2.22.2 Function

This register contains FLT\_ID1 target value, as well as IDE and RTR target values used to filter an incoming message ID. The FLT\_ID1 is used either for equal to, smaller than, greater than comparisons, or as the lower limit value in a ID range detection. It can be written in Freeze mode only.

### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | FLT_ID1            | —                      |
| FlexCAN1 | —                  | FLT_ID1                |
| FlexCAN2 | —                  | FLT_ID1                |

| 30<br>FLT_IDE   | ID Extended Filter<br>This bit identifies whether the frame format is standard or extended. It is used as part of the ID reception filter.<br>0b - Accept standard frame format<br>1b - Accept extended frame format                |
| 29<br>FLT_RTR   | Remote Transmission Request Filter<br>This bit identifies whether the frame is remote or not. It is used as part of the ID reception filter.<br>0b - Reject remote frame (accept data frame)<br>1b - Accept remote frame            |
| 28-0<br>FLT_ID1 | ID Filter 1 for Pretended Networking filtering<br>This 29-bit field defines either the 29 bits of an extended frame format, considering all bits, or the 11 bits of a standard frame format, considering just the 11 leftmost bits. |

## 55.5.2.23 Pretended Networking DLC Filter Register (FLT\_DLC)

### 55.5.2.23.1 Offset

| Register | Offset |
|----------|--------|
| FLT_DLC  | B10h   |

### 55.5.2.23.2 Function

This register contains the DLC inside range target values (FLT\_DLC\_LO and FLT\_DLC\_HI) used to filter an incoming message. The DLC range is used only for payload filtering. It can be written in Freeze mode only.

#### NOTE

When a fixed quantity of data bytes is required, both FLT\_DLC\_LO and FLT\_DLC\_HI need to be configured with the same value, otherwise a range of DLC is considered for filtering (see [Receive process under Pretended Networking mode](#)).

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | FLT_DLC            | —                      |
| FlexCAN1 | —                  | FLT_DLC                |
| FlexCAN2 | —                  | FLT_DLC                |

| 19-16<br>FLT_DLC_LO | Lower Limit for Length of Data Bytes Filter<br>This field specifies the lower limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter. |
| 15-4<br>—           | Reserved                                                                                                                                                                                                  |
| 3-0<br>FLT_DLC_HI   | Upper Limit for Length of Data Bytes Filter<br>This field specifies the upper limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter. |

### 55.5.2.24 Pretended Networking Payload Low Filter 1 Register (PL1\_LO)

### 55.5.2.24.1 Offset

| Register | Offset |
|----------|--------|
| PL1_LO   | B14h   |

### 55.5.2.24.2 Function

This register contains payload filter 1 low order bits of the target value used to filter incoming message payload. It is used either for “equal to”, “smaller than or equal”, “greater than or equal” comparisons, or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | PL1_LO             | —                      |
| FlexCAN1 | —                  | PL1_LO                 |
| FlexCAN2 | —                  | PL1_LO                 |

## 55.5.2.25 Pretended Networking Payload High Filter 1 Register (PL1\_HI)

### 55.5.2.25.1 Offset

| Register | Offset |
|----------|--------|
| PL1_HI   | B18h   |

### 55.5.2.25.2 Function

This register contains payload filter 1 high order bits of the target value used to filter incoming message payload. It is used either for equal to, smaller than or equal to, greater than or equal to comparisons, or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

## NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | PL1_HI             | —                      |
| FlexCAN1 | —                  | PL1_HI                 |
| FlexCAN2 | —                  | PL1_HI                 |

### 55.5.2.25.3 Diagram

### 55.5.2.25.4 Fields

| Field                | Function                                                                                                  |
|----------------------|-----------------------------------------------------------------------------------------------------------|
| 31-24<br>Data_byte_4 | Payload Filter 1 high order bits for Pretended Networking payload filtering corresponding to data byte 4. |
| 23-16<br>Data_byte_5 | Payload Filter 1 high order bits for Pretended Networking payload filtering corresponding to data byte 5. |
| 15-8<br>Data_byte_6  | Payload Filter 1 high order bits for Pretended Networking payload filtering corresponding to data byte 6. |
| 7-0<br>Data_byte_7   | Payload Filter 1 high order bits for Pretended Networking payload filtering corresponding to data byte 7. |

## 55.5.2.26 Pretended Networking ID Filter 2 Register / ID Mask Register (FLT\_ID2\_IDMASK)

### 55.5.2.26.1 Offset

| Register       | Offset |
|----------------|--------|
| FLT_ID2_IDMASK | B1Ch   |

### 55.5.2.26.2 Function

This register contains FLT\_ID2 target value used only as the upper limit value in ID range detection. Also, when exact ID filtering criteria is selected, this register is used to store the ID mask. IDE\_MSK and RTR\_MSK bits are used in both ID filtering (exact and

range) to enable FLT\_IDE and FLT\_RTR respectively to be used as part of ID reception filter. This register can be written in Freeze mode only.

## NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | FLT_ID2_IDMASK     | —                      |
| FlexCAN1 | —                  | FLT_ID2_IDMASK         |
| FlexCAN2 | —                  | FLT_ID2_IDMASK         |

| 28-0<br>FLT_ID2_IDMASK | <p>ID Filter 2 for Pretended Networking Filtering / ID Mask Bits for Pretended Networking ID Filtering</p> <p>This register is used to define either the ID filter value in extended frame format (29 bits), considering the FLT_ID2[28:0], or the ID filter value in standard frame format (11 bits), considering the FLT_ID2[28:18] (other bits in the [17:0] range have no meaning). Used only in range of ID filtering.</p> <p>It can also be used to define either the mask values for the extended frame format (29 bits), considering the IDMASK[28:0], or for the standard frame format (11 bits), considering the IDMASK[28:18] (other bits in the [17:0] range have no meaning). Used only in exact ID filtering.</p> |

### 55.5.2.27 Pretended Networking Payload Low Filter 2 Register / Payload Low Mask register (PL2\_PLMASK\_LO)

#### 55.5.2.27.1 Offset

| Register      | Offset |
|---------------|--------|
| PL2_PLMASK_LO | B20h   |

#### 55.5.2.27.2 Function

This register has two functions. First, it contains the low order bits for the payload filter 2 used only as the upper limit value in a payload range detection. Second, when exact payload filtering criteria is selected, this register is used as payload mask. Otherwise, this register is unused. It can be written in Freeze mode only.

### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | PL2_PLMASK_LO      | —                      |
| FlexCAN1 | —                  | PL2_PLMASK_LO          |
| FlexCAN2 | —                  | PL2_PLMASK_LO          |

**55.5.2.29 Wake Up Message Buffer register for C/S (WMB0\_CS - WMB3\_CS)**

### 55.5.2.29.1 Offset

| Register | Offset |
|----------|--------|
| WMB0_CS  | B40h   |
| WMB1_CS  | B50h   |
| WMB2_CS  | B60h   |
| WMB3_CS  | B70h   |

### 55.5.2.29.2 Function

Each of the four WMBs contains a register to store the Control Status (C/S) information (IDE, RTR, and DLC fields) of an incoming Rx message.

#### NOTE

The C/S registers are located at B40h for WMB0, B50h for WMB1, B60h for WMB2, and B70h for WMB3.

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | WMB0_CS–WMB3_CS    | —                      |
| FlexCAN1 | —                  | WMB0_CS–WMB3_CS        |
| FlexCAN2 | —                  | WMB0_CS–WMB3_CS        |

### 55.5.2.29.3 Diagram

| 19-16<br>DLC | Length of Data in Bytes<br>This 4-bit field is the length (in bytes) of the Rx data received when FlexCAN is in Pretended Networking mode. This 4-bit field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. The DLC field indicates which data bytes are valid. |
| 15-0<br>—    | Reserved                                                                                                                                                                                                                                                                                                              |

## 55.5.2.30 Wake Up Message Buffer Register for ID (WMB0\_ID - WMB3\_ID)

### 55.5.2.30.1 Offset

| Register | Offset |
|----------|--------|
| WMB0_ID  | B44h   |
| WMB1_ID  | B54h   |
| WMB2_ID  | B64h   |
| WMB3_ID  | B74h   |

### 55.5.2.30.2 Function

Each of the four WMBs contains a register to store the ID information of an incoming Rx message.

**NOTE**

The ID registers are located at B44h for WMB0, B54h for WMB1, B64h for WMB2, and B74h for WMB3.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | WMB0_ID–WMB3_ID    | —                      |
| FlexCAN1 | —                  | WMB0_ID–WMB3_ID        |
| FlexCAN2 | —                  | WMB0_ID–WMB3_ID        |

**55.5.2.30.3 Diagram****55.5.2.30.4 Fields**

| Field      | Function                                                                                                                                                                                                                                                                                            |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29<br>— | Reserved                                                                                                                                                                                                                                                                                            |
| 28-0<br>ID | Received ID under Pretended Networking mode<br>This register stores either the 29 bits of the extended frame format (considering the ID[28:0] field), or the 11 bits of the standard frame format (considering the ID[28:18] field only; the remaining bits in the ID[17:0] range have no meaning). |

### 55.5.2.31 Wake Up Message Buffer Register for Data 0-3 (WMB0\_D03 - WMB3\_D03)

#### 55.5.2.31.1 Offset

| Register | Offset |
|----------|--------|
| WMB0_D03 | B48h   |
| WMB1_D03 | B58h   |
| WMB2_D03 | B68h   |
| WMB3_D03 | B78h   |

#### 55.5.2.31.2 Function

Each of the four WMBs contains a register to store the data bytes 0 to 3 of the payload information of an incoming Rx message. This register's content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

#### NOTE

The Data 0-3 registers are located at B48h for WMB0, B58h for WMB1, B68h for WMB2, and B78h for WMB3.

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | WMB0_D03–WMB3_D03  | —                      |
| FlexCAN1 | —                  | WMB0_D03–WMB3_D03      |
| FlexCAN2 | —                  | WMB0_D03–WMB3_D03      |

## 55.5.2.32 Wake Up Message Buffer Register Data 4-7 (WMB0\_D47 - WMB3\_D47)

### 55.5.2.32.1 Offset

| Register | Offset |
|----------|--------|
| WMB0_D47 | B4Ch   |
| WMB1_D47 | B5Ch   |
| WMB2_D47 | B6Ch   |
| WMB3_D47 | B7Ch   |

### 55.5.2.32.2 Function

Each of the four WMBs contains a register to store the data bytes 4 to 7 of the payload information of an incoming Rx message. This register's content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

#### NOTE

The Data 4-7 registers are located at B4Ch for WMB0, B5Ch for WMB1, B6Ch for WMB2, and B7Ch for WMB3.

#### NOTE

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|----------|--------------------|------------------------|
| FlexCAN0 | WMB0_D47–WMB3_D47  | —                      |

### 55.5.2.33 CAN FD Control Register (FDCTRL)

#### 55.5.2.33.1 Offset

| Register | Offset |
|----------|--------|
| FDCTRL   | C00h   |

#### 55.5.2.33.2 Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

**Table 55-25. Number of message buffers**

| Payload size | Maximum number of message buffers per RAM block |
|--------------|-------------------------------------------------|
| 8 bytes      | 32                                              |
| 16 bytes     | 21                                              |
| 32 bytes     | 12                                              |
| 64 bytes     | 7                                               |

#### NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next

block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

| 5-0<br>TDCVAL   | <p>Transceiver Delay Compensation Value</p> <p>This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK).</p> <p>See <a href="#">Protocol timing</a> for more details on how the loop delay measurement is performed.</p>                                                                                                                                                                                                                                                                     |

## 55.5.2.34 CAN FD Bit Timing Register (FDCBT)

### 55.5.2.34.1 Offset

| Register | Offset |
|----------|--------|
| FDCBT    | C04h   |

### 55.5.2.34.2 Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRES DIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

#### NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

#### NOTE

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

## 55.5.2.35 CAN FD CRC Register (FDCRC)

### 55.5.2.35.1 Offset

| Register | Offset |
|----------|--------|
| FDCRC    | C08h   |

### 55.5.2.35.2 Function

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC\_15 polynomial is used for all frames in CAN format. The CRC\_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC\_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time the Tx Interrupt flag is asserted.

$$\begin{aligned} \text{CRC\_15} &= \text{C599h: } (x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1) \\ \text{CRC\_17} &= \text{3685Bh: } (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1) \\ \text{CRC\_21} &= \text{302899h: } (x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1) \end{aligned}$$

**Figure 55-28. CRC polynomial used on CAN frame**

### NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

| 20-0<br>FD_TXCRC  | Extended Transmitted CRC value<br>This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes.<br><br>For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively.<br><br>For CRC_15, this register has the same content as CRC register. |

The memory area 80h–27Fh is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See [FlexCAN memory partition for CAN FD](#) for more detailed information.

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 1010b (see table below).

This bit defines whether the bit rate is switched inside a CAN FD format frame.

**ESI** — Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

**CODE** — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 55-27](#) and [Table 55-28](#). See [Functional description](#) for additional information.

|                                                                                                                                                |                                  |                  |                                                 |                  | for details about overrun behavior.                                                                                                                                                                                                                                                                                                                          |
| 0110b: OVERRUN<br>— MB is being overwritten into a full buffer.                                                                                | OVERRUN                          | Yes              | FULL                                            | —                | If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.                                                                                                                                                                                                                          |
|                                                                                                                                                |                                  | No               | OVERRUN                                         | —                | If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.                                                                                                                               |
| 1010b: RANSWER <sup>4</sup> — A frame was configured to recognize a Remote Request frame and transmit a Response frame in return. <sup>5</sup> | RANSWER                          | —                | TANSWER(1110b)                                  | 0                | A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110b). See <a href="#">Matching process</a> for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received. |
|                                                                                                                                                |                                  | —                | —                                               | 1                | This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.                                                                                                                                                                                                                                              |

**Table 55-27. Message buffer code for Rx buffers (continued)**

| CODE description                                                                                 | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment                                                                                                             |
|--------------------------------------------------------------------------------------------------|----------------------------------|------------------|-------------------------------------------------|------------------|---------------------------------------------------------------------------------------------------------------------|
| CODE[0]=1: BUSY<br>— FlexCAN is updating the contents of the MB. The CPU must not access the MB. | BUSY <sup>6</sup>                | —                | FULL                                            | —                | Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE. |
|                                                                                                  |                                  | —                | OVERRUN                                         | —                |                                                                                                                     |

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit, see "Control 2 register (CTRL2)" for details.
4. Code 1010b is not considered Tx and an MB with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 55-28. Message buffer code for Tx buffers**

| CODE Description                                                                 | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment                                                                                                                                                                                               |
|----------------------------------------------------------------------------------|-------------------------|--------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000b: INACTIVE — MB is not active                                               | INACTIVE                | —      | —                                     | MB does not participate in arbitration process.                                                                                                                                                       |
| 1001b: ABORT — MB is aborted                                                     | ABORT                   | —      | —                                     | MB does not participate in arbitration process.                                                                                                                                                       |
| 1100b: DATA — MB is a Tx data frame (MB RTR must be 0)                           | DATA                    | 0      | INACTIVE                              | Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.                                                                                     |
| 1100b: REMOTE — MB is a Tx Remote Request frame (MB RTR must be 1)               | REMOTE                  | 1      | EMPTY                                 | Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.                                                                 |
| 1110b: TANSWER — MB is a Tx Response frame from an incoming Remote Request frame | TANSWER                 | —      | RANSWER                               | This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, |

**Table 55-28. Message buffer code for Tx buffers**

| CODE Description | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment                                                                                                                                                                                                                                                                                                                               |
|------------------|-------------------------|--------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |                         |        |                                       | and then the code will automatically return to RANSWER (1010b). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details. |

**SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 55-27](#), [Table 55-28](#), and the description of the RRS field in Control 2 register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### NOTE

When configuring CAN FD frames, the RTR bit must be negated.

### DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 8h–Fh of the MB space (see [Table 55-26](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 55-29](#)).

### TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### PRI0 — Local priority

This 3-bit field is used only when MCR[LPRI0\_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### DATA BYTE 0 to 63 — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

**Table 55-29. DATA BYTEs validity**

| DLC | Valid DATA BYTEs  |
|-----|-------------------|
| 0   | none              |
| 1   | DATA BYTE 0       |
| 2   | DATA BYTE 0 to 1  |
| 3   | DATA BYTE 0 to 2  |
| 4   | DATA BYTE 0 to 3  |
| 5   | DATA BYTE 0 to 4  |
| 6   | DATA BYTE 0 to 5  |
| 7   | DATA BYTE 0 to 6  |
| 8   | DATA BYTE 0 to 7  |
| 9   | DATA BYTE 0 to 11 |
| 10  | DATA BYTE 0 to 15 |
| 11  | DATA BYTE 0 to 19 |
| 12  | DATA BYTE 0 to 23 |
| 13  | DATA BYTE 0 to 31 |
| 14  | DATA BYTE 0 to 47 |
| 15  | DATA BYTE 0 to 63 |

### 55.5.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL[MBDSRn] bit fields as shown in table below.

**Table 55-30. RAM partition**

| RAM block | Number of MBs with 8 bytes (default range) | Size control bit field in FDCTRL register | Number of MBs of different sizes, per block                                                                                                                            |
|-----------|--------------------------------------------|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | 0 to 31                                    | MBDSR0                                    | MBDSR0=00, 32 MBs with 8 bytes payload<br>MBDSR0=01, 21 MBs with 16 bytes payload<br>MBDSR0=10, 12 MBs with 32 bytes payload<br>MBDSR0=11, 7 MBs with 64 bytes payload |

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Then the following table indicates how the message buffers will be arranged in RAM.

**Table 55-31. RAM partition example**

| RAM block | Payload size                       | Number of MBs in the RAM block | Message buffer range |
|-----------|------------------------------------|--------------------------------|----------------------|
| 0         | FDCTRL[MBDSR0]=00, 8 bytes payload | 32                             | 0 to 31              |

### 55.5.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

**Table 55-32. 8-byte message buffers**

| Address offset (hex) | MBDSR=b00<br>8-byte payload |
|----------------------|-----------------------------|
| 0080                 | MB0                         |
| 0090                 | MB1                         |
| 00A0                 | MB2                         |
| 00B0                 | MB3                         |
| 00C0                 | MB4                         |
| 00D0                 | MB5                         |
| 00E0                 | MB6                         |
| 00F0                 | MB7                         |
| 0100                 | MB8                         |
| 0110                 | MB9                         |
| 0120                 | MB10                        |
| 0130                 | MB11                        |
| 0140                 | MB12                        |
| 0150                 | MB13                        |
| 0160                 | MB14                        |
| 0170                 | MB15                        |
| 0180                 | MB16                        |
| 0190                 | MB17                        |
| 01A0                 | MB18                        |

## 55.5.6 Rx FIFO structure

When MCR[RFEN] is set, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 80h–8Ch contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 55-36. Rx FIFO structure**

| 31       |  | 28                                |                             | 24 |  | 23 |  | 22          |  | 21  |  | 20  |  | 19  |             | 18 |  | 17 |  | 16          |  | 15 |  | 8 |  | 7           |  | 0 |  |  |  |

| E4h      |  | ID filter table element 1         |                             |    |  |    |  |             |  |     |  |     |  |     |             |    |  |    |  |             |  |    |  |   |  |             |  |   |  |  |  |
| E8h–2D4h |  | ID filter table elements 2 to 125 |                             |    |  |    |  |             |  |     |  |     |  |     |             |    |  |    |  |             |  |    |  |   |  |             |  |   |  |  |  |
| 2D8h     |  | ID filter table element 126       |                             |    |  |    |  |             |  |     |  |     |  |     |             |    |  |    |  |             |  |    |  |   |  |             |  |   |  |  |  |
| 2DCh     |  | ID filter table element 127       |                             |    |  |    |  |             |  |     |  |     |  |     |             |    |  |    |  |             |  |    |  |   |  |             |  |   |  |  |  |
|          |  |                                   | = Unimplemented or reserved |    |  |    |  |             |  |     |  |     |  |     |             |    |  |    |  |             |  |    |  |   |  |             |  |   |  |  |  |

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

**Table 55-37. ID table structure**

| Format | 31                           | 30  | 29                                              | 24 | 23                           | 16 | 15  | 14                          | 13                                            | 8 | 7 | 1                          | 0 |
|--------|------------------------------|-----|-------------------------------------------------|----|------------------------------|----|-----|-----------------------------|-----------------------------------------------|---|---|----------------------------|---|
| A      | RTR                          | IDE | RXIDA<br>(standard = 29–19, extended = 29–1)    |    |                              |    |     |                             |                                               |   |   |                            |   |
| B      | RTR                          | IDE | RXIDB_0<br>(standard = 29–19, extended = 29–16) |    |                              |    | RTR | IDE                         | RXIDB_1<br>(standard = 13–3, extended = 13–0) |   |   |                            |   |
| C      | RXIDC_0<br>(std/ext = 31–24) |     |                                                 |    | RXIDC_1<br>(std/ext = 23–16) |    |     | RXIDC_2<br>(std/ext = 15–8) |                                               |   |   | RXIDC_3<br>(std/ext = 7–0) |   |
|        |                              |     | = Unimplemented or Reserved                     |    |                              |    |     |                             |                                               |   |   |                            |   |

**RTR** — Remote frame

This bit specifies if remote frames are accepted into the FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

**IDE** — Extended frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

**RXIDA** — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

**RXIDB\_0, RXIDB\_1** — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

**RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx frame identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

**IDHIT** — Identifier acceptance filter hit indicator

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. See [Rx FIFO](#) for more information.

## 55.6 Initialization/application information

This section provides instructions for initializing the FlexCAN module.

## 55.6.1 FlexCAN initialization sequence

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see [Freeze mode](#)). Note that the module needs to be initialized after every reset.

The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
  - a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
  - b. Enable the warning interrupts by setting WRNEN.
  - c. If required, disable frame self reception by setting SRXDIS.
  - d. Enable the Rx FIFO by setting RFEN.
  - e. If Rx FIFO is enabled and DMA is required, set DMA.
  - f. If Pretended Networking mode is required, set PNET\_EN.
  - g. Enable the abort mechanism by setting AEN.
  - h. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
  - a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
  - b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
  - c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
  - d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
  - e. Determine the CAN FD bit rate by programming the FPRESDIV field.
  - f. Determine the internal arbitration mode (LBUF).
3. Initialize the message buffers.
  - a. The control and status word of all message buffers must be initialized.
  - b. If Rx FIFO was enabled, the ID filter table must be initialized.
  - c. Other entries in each message buffer should be initialized as required.
4. Initialize the Rx Individual Mask registers (RXIMRn).
5. Set required interrupt mask bits in
  - IMASK registers (for all MB interrupts)
  - CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)
6. If Pretended Networking mode is enabled, configure the necessary registers for selective wakeup.
7. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

## Chapter 56

# Synchronous Audio Interface (SAI)

### 56.1 Chip-specific SAI information

S32K148 has two instances of the SAI module. Other products in the S32K1xx series do not have the SAI module.

#### 56.1.1 SAI configuration

- S32K148 has 2 SAI modules: SAI0, SAI1.
  - SAI0 and SAI1 will always operate asynchronously with respect to each other, which means that SAI0 will operate asynchronously with respect to SAI1, and SAI1 will operate asynchronously with respect to SAI0.
  - The SAI\_BCLK (SAI\_TX\_BCLK, SAI\_RX\_BCLK), SAI\_SYNC (SAI\_TX\_SYNC, SAI\_RX\_SYNC), and SAI\_DATA (SAI\_TX\_DATA, SAI\_RX\_DATA) pins are shared between each module instance's (SAI0, SAI1) receiver and transmitter on S32K148 devices. See the IO Signal Description Input Multiplexing sheet(s) attached to this Reference Manual for details. At any specific time, either the SAI receiver or the SAI transmitter should be active or they should operate synchronously (only one active at a time). The SAI transmitter and SAI receiver should not be configured to operate simultaneously with inconsistent configurations (as mentioned previously).
- Other devices in the S32K14x series do not have any SAI modules; only S32K148 devices have SAI modules.

**Table 56-1. SAI module configurations**

| Feature               | SAI0 module                         | SAI1 module                         |
|-----------------------|-------------------------------------|-------------------------------------|
| Channels supported    | 4                                   | 1                                   |
| FIFO size             | 8 words                             | 8 words                             |
| FRAME length          | Maximum = 16 words per frame        | Maximum = 16 words per frame        |
| Frame Synchronization | I2S, AC97, and CODEC/DSP interfaces | I2S, AC97, and CODEC/DSP interfaces |

**NOTE**

- SAI functionality is not supported in STOP/VLPS modes.
- Before using SAI\_TX\_DATAx (SAI\_Dx), SAI\_SYNC, or SAI\_BCLK for input configurations, GPIO\_PDDR must be configured for the corresponding pins.
- To correctly generate the SAI's internal bit clock when TCR2[BCI] bit is set, TCR2[SYNC] must be set to 0x01 in either receiver or transmitter configuration.
- If the SAI\_BCLK is enabled with bit fields RCR2[DIV]/TCR2[DIV] > 0 and then disabled by either software or stop mode entry, a software reset of SAI must be issued when enabling the SAI\_BCLK. Otherwise, SAI\_BCLK will not be generated correctly.

**Figure 56-1. S32K148 SAI Block Diagram**

## 56.1.2 Chip-specific register information

The reset value of the PARAM register varies for the two SAI module instances. The following table shows the instance-specific reset values.

**Table 56-2. SAI register reset values**

| Instance | PARAM reset value | Comment                                          |
|----------|-------------------|--------------------------------------------------|
| SAI0     | 0004_0304         | PARAM[DATA LINE] reflects support for 4 channels |
| SAI1     | 0004_0301         | PARAM[DATA LINE] reflects support for 1 channel  |

## 56.2 Introduction

The I<sup>2</sup>S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I<sup>2</sup>S, AC97, TDM, and codec/DSP interfaces.

### 56.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 4 data lines
- Receiver with independent bit clock and frame sync supporting 4 data lines
- Each data line can support a maximum Frame size of 16 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 8 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO

### 56.2.2 Block diagram

The following block diagram also shows the module clocks.

Figure 56-2. I²S/SAI block diagram

### 56.2.3 Modes of operation

Module power modes include Run mode, and Debug mode.

#### 56.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

#### 56.2.3.2 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 56.3 External signals

| Name         | Function                                                                                                                                                                                           | I/O |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| TX_BCLK      | Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.                                                                                   | I/O |
| TX_SYNC      | Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| TX_DATA[3:0] | Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.                                                                    | O   |
| RX_BCLK      | Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.                                                                                    | I/O |
| RX_SYNC      | Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.  | I/O |
| RX_DATA[3:0] | Receive Data. The receive data is sampled synchronously by the bit clock.                                                                                                                          | I   |

## 56.4 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

### 56.4.1 I2S register descriptions

#### 56.4.1.1 I2S memory map

SAI0 base address: 4005\_4000h

SAI1 base address: 4005\_5000h

| 27-24<br>CFR       | <p>Channel FIFO Reset</p> <p>Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.</p> <p>The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer.</p> <p>0b - No effect.<br/>1b - Transmit data channel N FIFO is reset.</p> <p><b>NOTE:</b> This field is not supported in every instance. | 19-16<br>TCE       | <p>Transmit Channel Enable</p> <p>Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.</p> <p>The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N.</p> <p>0b - Transmit data channel N is disabled.<br/>1b - Transmit data channel N is enabled.</p> <p><b>NOTE:</b> This field is not supported in every instance. The following table includes only supported registers.</p> <table> <tr> <th>Field supported in</th><th>Field not supported in</th></tr> <tr> <td>SAI0_TCR3</td><td>—</td></tr> <tr> <td>SAI1_TCR3[16]</td><td>SAI1_TCR3[19–17]</td></tr> </table> | Field supported in | Field not supported in | SAI0_TCR3 | — | SAI1_TCR3[16] | SAI1_TCR3[19–17] |

| 3-0<br>WDFL        | <p>Word Flag Configuration</p> <p>Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                        |           |   |               |                  |

## 56.4.1.8 SAI Transmit Configuration 4 Register (TCR4)

### 56.4.1.8.1 Offset

| Register | Offset |
|----------|--------|
| TCR4     | 18h    |

### 56.4.1.8.2 Function

This register must not be altered when TCSR[TE] is set.

### 56.4.1.8.3 Diagram

| 28<br>FCONT    | FIFO Continue on Error<br>Configures when the SAI will continue transmitting after a FIFO error has been detected.<br>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.                                                                                                                                   |
| 27-26<br>FCOMB | FIFO Combine Mode<br>When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. |

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|------------------------|-----------|---|---|-----------|
|                    | <p>When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.</p> <p><b>NOTE:</b> This field is not supported in every instance. The following table includes only supported registers.</p> <table> <tr> <th>Field supported in</th><th>Field not supported in</th></tr> <tr> <td>SAI0_TCR4</td><td>—</td></tr> <tr> <td>—</td><td>SAI1_TCR4</td></tr> </table> <p>00b - FIFO combine mode disabled.<br/> 01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers).<br/> 10b - FIFO combine mode enabled on FIFO writes (by software).<br/> 11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).</p> | Field supported in | Field not supported in | SAI0_TCR4 | — | — | SAI1_TCR4 |

| 25-24<br>FPACK     | <p>FIFO Packing Mode</p> <p>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.</p> <p>00b - FIFO packing is disabled<br/> 01b - Reserved<br/> 10b - 8-bit FIFO packing is enabled<br/> 11b - 16-bit FIFO packing is enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                        |           |   |   |           |

### 56.4.1.10 SAI Transmit Data Register (TDR0 - TDR3)

### 56.4.1.10.1 Offset

| Register | Offset |
|----------|--------|
| TDR0     | 20h    |
| TDR1     | 24h    |
| TDR2     | 28h    |
| TDR3     | 2Ch    |

#### NOTE

Each module instance supports a different number of registers.

| Register supported     | Register not supported |
|------------------------|------------------------|
| SAI0_T<br>DR0–<br>TDR3 | —                      |
| SAI1_T<br>DR0          | SAI1_T<br>DR1–<br>TDR3 |

### 56.4.1.10.2 Diagram

### 56.4.1.10.3 Register reset values

| Register  | Reset value           |
|-----------|-----------------------|
| TDR0      | SAI0,SAI1: 0000_0000h |
| TDR1–TDR3 | 0000_0000h            |

### 56.4.1.10.4 Fields

| Field | Function                                                                                                                                                                               |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | Transmit Data Register                                                                                                                                                                 |
| TDR   | Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored. |

### 56.4.1.11 SAI Transmit FIFO Register (TFR0 - TFR3)

#### 56.4.1.11.1 Offset

| Register | Offset |
|----------|--------|
| TFR0     | 40h    |
| TFR1     | 44h    |
| TFR2     | 48h    |
| TFR3     | 4Ch    |

#### 56.4.1.11.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

### NOTE

Each module instance supports a different number of registers.

| Register supported     | Register not supported |
|------------------------|------------------------|
| SAI0_T<br>FR0–<br>TFR3 | —                      |
| SAI1_T<br>FR0          | SAI1_T<br>FR1–<br>TFR3 |

### 56.4.1.11.3 Diagram

### 56.4.1.11.4 Register reset values

| Register  | Reset value           |
|-----------|-----------------------|
| TFR0      | SAI0,SAI1: 0000_0000h |
| TFR1–TFR3 | 0000_0000h            |

| Field | Function                                     |
|-------|----------------------------------------------|
| 3-0   | Read FIFO Pointer                            |
| RFP   | FIFO read pointer for transmit data channel. |

### 56.4.1.12 SAI Transmit Mask Register (TMR)

#### 56.4.1.12.1 Offset

| Register | Offset |
|----------|--------|
| TMR      | 60h    |

#### 56.4.1.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

| 28<br>BCI     | Bit Clock Input<br>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.<br><br>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock .<br><br>0b - No effect.<br>1b - Internal logic is clocked as if bit clock was externally generated. |
| 27-26<br>MSEL | MCLK Select<br>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.<br><br><b>NOTE:</b> Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option.<br>00b - Bus Clock selected.<br>01b - Master Clock (MCLK) 1 option selected.<br>10b - Master Clock (MCLK) 2 option selected.<br>11b - Master Clock (MCLK) 3 option selected.                                                                                                                                                                                                                                                                                         |
| 25<br>BCP     | Bit Clock Polarity<br>Configures the polarity of the bit clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 3-0<br>WDFL        | <p>Word Flag Configuration</p> <p>Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                        |           |   |               |                  |

### 56.4.1.17 SAI Receive Configuration 4 Register (RCR4)

#### 56.4.1.17.1 Offset

| Register | Offset |
|----------|--------|
| RCR4     | 98h    |

#### 56.4.1.17.2 Function

This register must not be altered when RCSR[RE] is set.

| 31-29<br>—     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 28<br>FCONT    | FIFO Continue on Error<br>Configures when the SAI will continue receiving after a FIFO error has been detected.<br>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.                                                                                                                              |
| 27-26<br>FCOMB | FIFO Combine Mode<br>When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. |

|                    | <p>When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.</p> <p><b>NOTE:</b> This field is not supported in every instance. | 25-24<br>FPACK     | <p>FIFO Packing Mode</p> <p>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.</p> <p>00b - FIFO packing is disabled<br/> 01b - Reserved.<br/> 10b - 8-bit FIFO packing is enabled<br/> 11b - 16-bit FIFO packing is enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                        |           |   |   |           |

| 12-8<br>FBT  | First Bit Shifted<br>Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. |
| 7-0<br>—     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 56.4.1.19 SAI Receive Data Register (RDR0 - RDR3)

#### 56.4.1.19.1 Offset

| Register | Offset |
|----------|--------|
| RDR0     | A0h    |
| RDR1     | A4h    |
| RDR2     | A8h    |
| RDR3     | ACh    |

### NOTE

Each module instance supports a different number of registers.

| Register supported     | Register not supported |
|------------------------|------------------------|
| SAI0_R<br>DR0–<br>RDR3 | —                      |
| SAI1_R<br>DR0          | SAI1_R<br>DR1–<br>RDR3 |

### 56.4.1.19.2 Diagram

### 56.4.1.19.3 Register reset values

| Register  | Reset value           |
|-----------|-----------------------|
| RDR0      | SAI0,SAI1: 0000_0000h |
| RDR1–RDR3 | 0000_0000h            |

### 56.4.1.19.4 Fields

| Field | Function                                                                                                                                                                                |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0  | Receive Data Register                                                                                                                                                                   |
| RDR   | Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored. |

## 56.4.1.20 SAI Receive FIFO Register (RFR0 - RFR3)

### 56.4.1.20.1 Offset

| Register | Offset |
|----------|--------|
| RFR0     | C0h    |
| RFR1     | C4h    |
| RFR2     | C8h    |
| RFR3     | CCh    |

### 56.4.1.20.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

### NOTE

Each module instance supports a different number of registers.

| Register supported     | Register not supported |
|------------------------|------------------------|
| SAI0_R<br>FR0–<br>RFR3 | —                      |
| SAI1_R<br>FR0          | SAI1_R<br>FR1–<br>RFR3 |

## 56.4.1.21 SAI Receive Mask Register (RMR)

### 56.4.1.21.1 Offset

| Register | Offset |
|----------|--------|
| RMR      | E0h    |

56.4.1.21.2 Function

This register is double-buffered and updates:

- 1. When RCSR[RE] is first set
- 2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

56.5 Functional description

This section provides a complete functional description of the block.

56.5.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

### 56.5.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

### 56.5.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

### **56.5.1.3 Bus clock**

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

#### **NOTE**

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

## **56.5.2 SAI resets**

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

### **56.5.2.1 Software reset**

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

### **56.5.2.2 FIFO reset**

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

### 56.5.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

#### 56.5.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

### **56.5.4 Frame sync configuration**

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 16 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

### **56.5.5 Data FIFO**

Each transmit and receive channel includes a FIFO of size 8 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

### 56.5.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 56-3](#) for LSB First configurations and [Figure 56-4](#) for MSB First configurations.

**Figure 56-3. SAI first bit shifted, LSB first**

Figure 56-4. SAI first bit shifted, MSB first

### 56.5.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR<sub>n</sub>), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR<sub>n</sub>) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR<sub>n</sub>), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR<sub>n</sub>) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

### 56.5.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset \$0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset \$2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset \$0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset \$2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset \$0, second word in byte offset \$1, third word in byte offset \$2 and fourth word in byte offset \$3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset \$0.

#### 56.5.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

## 56.5.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

## 56.5.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

### 56.5.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

### 56.5.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### 56.5.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

### 56.5.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

### 56.5.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

## Chapter 57

# Ethernet MAC (ENET)

### 57.1 Chip-specific ENET information

S32K148 has one instance of the ENET module. Other products in the S32K1xx series do not have the ENET module.

#### NOTE

- Prior to using ENET\_MDIO or ENET\_TMRx, GPIO\_PDDR needs to be configured for the corresponding pins.
- Enable the Drive strength for the transmitting pads of ENET by setting DSE field of PORT\_PCRn register
- Wakeup through magic packet is supported only from STOPx modes and not from VLPS mode. This wakeup is independent of EIMR[WAKEUP] bit field.
- For RMII mode, MII\_RMII\_TX\_CLK in IO Signal Description Input Multiplexing sheet is referred as RMII\_REF\_CLK.

#### 57.1.1 Software guideline during ENET operation

System frequency must not be changed during ENET operation as this can cause FIFO Underrun condition.

### 57.2 Introduction

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

## 57.3 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

### 57.3.1 Features

#### 57.3.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:

- a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
- a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
- a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors

### 57.3.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

### 57.3.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames

- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

### 57.3.2 Block diagram

Figure 57-1. Ethernet MAC-NET core block diagram

## 57.4 External signal description

### NOTE

The MII column pertains only to devices that support MII.

## External signal description

| MII          | RMII          | Description                                                                                                                                                                                                                                                                                                       | I/O |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII_COL      | —             | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.                                                                                                                                                                        | I   |
| MII_CRS      | —             | Carrier sense. When asserted, indicates transmit or receive medium is not idle.<br><br>In RMII mode, this signal is present on the RMII_CRS_DV pin.                                                                                                                                                               | I   |
| MII_MDC      | RMII_MDC      | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.                                                                                                                                                                                                                        | O   |
| MII_MDIO     | RMII_MDIO     | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.                                                                                                                                                          | I/O |
| MII_RXCLK    | —             | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.                                                                                                                                                                                                                                            | I   |
| MII_RXDV     | RMII_CRS_DV   | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| MII_RXD[3:0] | RMII_RXD[1:0] | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.                                                                                                                                                                                                   | I   |
| MII_RXER     | RMII_RXER     | When asserted with RXDV, indicates the PHY detects an error in the current frame.                                                                                                                                                                                                                                 | I   |
| MII_TXCLK    | —             | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.                                                                                                                                                                                                                                      | I   |
| MII_TXD[3:0] | RMII_TXD[1:0] | Serial output Ethernet data. Only valid during TXEN assertion.                                                                                                                                                                                                                                                    | O   |
| MII_TXEN     | RMII_TXEN     | Indicates when valid nibbles are present on the MII. This signal is asserted with the                                                                                                                                                                                                                             | O   |

Table continues on the next page...

| MII                   | RMII                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | I/O |
|-----------------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
|                       |                       | first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |
| MII_TXER              | —                     | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | O   |
| —                     | RMII_REF_CLK          | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | I   |
| 1588_TMR <sub>n</sub> | 1588_TMR <sub>n</sub> | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<sub>n</sub> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<sub>n</sub> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<sub>n</sub>.</p> <p>An interrupt can be triggered if ENET_TCSR<sub>n</sub>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<sub>n</sub>[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN       | ENET_1588_CLKIN       | Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | I   |

## 57.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 57-1. Register map summary**

| Offset Address  | Section               | Description                                            |
|-----------------|-----------------------|--------------------------------------------------------|
| 0x0000 – 0x01FF | Configuration         | Core control and status registers                      |
| 0x0200 – 0x03FF | Statistics counters   | MIB and Remote Network Monitoring (RFC 2819) registers |
| 0x0400 – 0x0430 | 1588 control          | 1588 adjustable timer (TSM) and 1588 frame control     |
| 0x0600 – 0x07FC | Capture/Compare block | Registers for the Capture/Compare block                |

**ENET memory map**

| Address offset (hex) | Register name                                              | Width (in bits) | Access | Reset value | Section/ page                |
|----------------------|------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 4                    | Interrupt Event Register (ENET_EIR)                        | 32              | w1c    | 0000_0000h  | <a href="#">57.5.1/2008</a>  |
| 8                    | Interrupt Mask Register (ENET_EIMR)                        | 32              | R/W    | 0000_0000h  | <a href="#">57.5.2/2011</a>  |
| 10                   | Receive Descriptor Active Register (ENET_RDAR)             | 32              | R/W    | 0000_0000h  | <a href="#">57.5.3/2014</a>  |
| 14                   | Transmit Descriptor Active Register (ENET_TDAR)            | 32              | R/W    | 0000_0000h  | <a href="#">57.5.4/2015</a>  |

**57.5.1 Interrupt Event Register (ENET\_EIR)**

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

**NOTE**

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

**ENET\_EIR field descriptions**

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                   |
| 30<br>BABR     | Babbling Receive Error<br>Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.                                                                                                                                                                                                                                                                                                                                      |
| 29<br>BABT     | Babbling Transmit Error<br>Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.                                                                                                                                                                                                        |
| 28<br>GRA      | Graceful Stop Complete<br>This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop.<br><b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again. |
| 27<br>TXF      | Transmit Frame Interrupt<br>Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                         |
| 26<br>TXB      | Transmit Buffer Interrupt<br>Indicates a transmit buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                                                                     |
| 25<br>RXF      | Receive Frame Interrupt<br>Indicates a frame has been received and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                             |

## ENET\_EIR field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24<br>RXB         | Receive Buffer Interrupt<br><br>Indicates a receive buffer descriptor is not the last in the frame has been updated.                                                                                                                                                                                                                                                                                                                                                                                                   |
| 23<br>MII         | MII Interrupt.<br><br>Indicates that the MII has completed the data transfer requested.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 22<br>EBERR       | Ethernet Bus Error<br><br>Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.                                                                                                                                                                                                             |
| 21<br>LC          | Late Collision<br><br>Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.                                                                                                                                                                                                                                                                                                                      |
| 20<br>RL          | Collision Retry Limit<br><br>Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.                                                                                                                                                                                                                                                     |
| 19<br>UN          | Transmit FIFO Underrun<br><br>Indicates the transmit FIFO became empty before the complete frame was transmitted.<br><br><b>NOTE:</b> In situations where the device has various masters generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See <a href="#">STRFWD</a> . Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module. |
| 18<br>PLR         | Payload Receive Error<br><br>Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.                                                                                                                                                                                                                                                                                                                                                |
| 17<br>WAKEUP      | Node Wakeup Request Indication<br><br>Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.                                                                                                                                                                                                                                                                                                                                                                    |
| 16<br>TS_AVAIL    | Transmit Timestamp Available<br><br>Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.                                                                                                                                                                                                                                                                                                                                                                             |
| 15<br>TS_TIMER    | Timestamp Timer<br><br>The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].                                                                                                                                                                                                                                              |
| 14–13<br>Reserved | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0.                                                                                                                                                                                                                                                                                                                                                                                                              |

**57.5.2 Interrupt Mask Register (ENET\_EIMR)**

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 0h base + 8h offset = 8h

### 57.5.4 Transmit Descriptor Active Register (ENET\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 0h base + 14h offset = 14h

## 57.5.5 Ethernet Control Register (ENET\_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 0h base + 24h offset = 24h

## 57.5.6 MII Management Frame Register (ENET\_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 0h base + 40h offset = 40h

## 57.5.7 MII Speed Control Register (ENET\_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 57-2. Programming Examples for MSCR**

| Internal module clock frequency | MSCR [MII_SPEED] | MDC frequency |
|---------------------------------|------------------|---------------|
| 25 MHz                          | 0x4              | 2.50 MHz      |
| 33 MHz                          | 0x6              | 2.36 MHz      |
| 40 MHz                          | 0x7              | 2.50 MHz      |
| 50 MHz                          | 0x9              | 2.50 MHz      |
| 66 MHz                          | 0xD              | 2.36 MHz      |

### 57.5.8 MIB Control Register (ENET\_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB\_DIS field resets to 1.

Address: 0h base + 64h offset = 64h

DRT must be cleared.</p> |

### 57.5.10 Transmit Control Register (ENET\_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 0h base + C4h offset = C4h

| 0<br>GTS       | <p>Graceful Transmit Stop</p> <p>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.</p> |

### 57.5.11 Physical Address Lower Register (ENET\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 0h base + E4h offset = E4h

**ENET\_PALR field descriptions**

| Field  | Description                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PADDR1 | Pause Address<br><br>Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames. |

### 57.5.12 Physical Address Upper Register (ENET\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 0h base + E8h offset = E8h

**ENET\_PAUR field descriptions**

| Field           | Description                                                                                                                                  |

| 31–16<br>PADDR2 | Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames. |
| TYPE            | Type Field In PAUSE Frames<br><br>These fields have a constant value of 0x8808.                                                              |

### 57.5.13 Opcode/Pause Duration Register (ENET\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 0h base + ECh offset = ECh

### 57.5.14 Descriptor Individual Upper Address Register (ENET\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

#### ENET\_GAUR field descriptions

| Field  | Description                                                                                                                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GADDR1 | Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32. |

57.5.17 Descriptor Group Lower Address Register (ENET\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 0h base + 124h offset = 124h

ENET\_GALR field descriptions

| Field  | Description                                                                                                                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0. |

57.5.18 Transmit FIFO Watermark Register (ENET\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: 0h base + 144h offset = 144h

**ENET\_TFWR field descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**57.5.19 Receive Descriptor Ring Start Register (ENET\_RDSR)**

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

**NOTE**

This register must be initialized prior to operation

## Memory map/register definition

Address: 0h base + 180h offset = 180h

## 57.5.20 Transmit Buffer Descriptor Ring Start Register (ENET\_TDSR)

TDSR provides a pointer to the beginning of the circular transmit buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

### NOTE

This register must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

**57.5.21 Maximum Receive Buffer Size Register (ENET\_MRBR)**

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

**NOTE**

This register must be initialized before operation.

Address: 0h base + 188h offset = 188h

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set. |

| TX_ALMOST_FULL   | Value Of The Transmit FIFO Almost Full Threshold<br><br>Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).<br><br>When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.<br><br><b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN. |

## 57.5.29 Transmit Inter-Packet Gap (ENET\_TIPG)

#### ENET\_FTRL field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                          |
| TRUNC_FL          | Frame Truncation Length<br><br>Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].<br><br><b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit. |

### 57.5.31 Transmit Accelerator Function Configuration (ENET\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 0h base + 1C0h offset = 1C0h

| Field | Description                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COUNT | Number of octets for frames received without error<br><br><b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR). |

**57.5.87 Adjustable Timer Control Register (ENET\_ATCR)**

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

**NOTE**

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

Address: 0h base + 400h offset = 400h

#### ENET\_ATPER field descriptions

| Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PERIOD | <p>Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (<math>1 \times 10^9</math>) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.</p> <p><b>NOTE:</b> The value of PERIOD has the following constraint:</p> $2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} > 0.$ |

## 57.5.91 Timer Correction Register (ENET\_ATCOR)

**ENET\_TCCR<sub>n</sub> field descriptions**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCC   | <p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p> |

## 57.6 Functional description

This section provides a complete functional description of the MAC-NET core.

### 57.6.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

**Figure 57-2. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

**Figure 57-3. VLAN-tagged MAC frame format overview****Table 57-3. MAC frame definition**

| Term                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame length                   | Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.                                                                                                                                                                                                                                                                                                                                                                 |
| Payload length                 | <p>The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.</p> <ul style="list-style-type: none"> <li>If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li> <li>If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li> </ul> |
| Destination and source address | 48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .                                                                                                                                                                                                                                                                                                                                                 |

## Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

### 57.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 57-4. Pause Frame Format (Values in Hex)**

|                |    |    |    |    |    |      |     |                               |    |    |    |          |    |
|----------------|----|----|----|----|----|------|-----|-------------------------------|----|----|----|----------|----|
| 1              | 2  | 3  | 4  | 5  | 6  | 7    | 8   | 9                             | 10 | 11 | 12 | 13       | 14 |
| 55             | 55 | 55 | 55 | 55 | 55 | 55   | D5  | 01                            | 80 | C2 | 00 | 00       | 01 |
| Preamble       |    |    |    |    |    |      | SFD | Multicast Destination Address |    |    |    |          |    |
| 15             | 16 | 17 | 18 | 19 | 20 | 21   | 22  | 23                            | 24 | 25 | 26 | 27 –68   |    |
| 00             | 00 | 00 | 00 | 00 | 00 | 88   | 08  | 00                            | 01 | hi | lo | 00       |    |
| Source Address |    |    |    |    |    | Type |     | Opcode                        |    | P1 | P2 | pad (42) |    |
| 69             | 70 | 71 | 72 |    |    |      |     |                               |    |    |    |          |    |
| 26             | 6B | AE | 0A |    |    |      |     |                               |    |    |    |          |    |
| CRC-32         |    |    |    |    |    |      |     |                               |    |    |    |          |    |

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 57.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

## 57.6.2 IP and higher layers frame format

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 57.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 57-5. Ethernet type value examples**

| Type   | Description                                                              |
|--------|--------------------------------------------------------------------------|
| 0x8100 | VLAN-tagged frame. The actual type is found 4 octets later in the frame. |
| 0x0800 | IPv4                                                                     |
| 0x0806 | ARP                                                                      |
| 0x86DD | IPv6                                                                     |

### 57.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 57-6. IPv4 header format**

|                     |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|-----|----|----|----|----------|----|----|----|----|----|----|----|-----------------|----|----|----|-----------------|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27  | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15              | 14 | 13 | 12 | 11              | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Version             |    |    |    | IHL |    |    |    | TOS      |    |    |    |    |    |    |    | Length          |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Fragment ID         |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    | Flags           |    |    |    | Fragment offset |    |   |   |   |   |   |   |   |   |   |   |
| TTL                 |    |    |    |     |    |    |    | Protocol |    |    |    |    |    |    |    | Header checksum |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Source address      |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Options             |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |

**Table 57-7. IPv4 header fields**

| Field name                          | Description                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version                             | 4-bit IP version information. 0x4 for IPv4 frames.                                                                                                           |
| IHL                                 | 4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5. |
| TOS                                 | Type of service/DiffServ field.                                                                                                                              |
| Length                              | Total length of the datagram in bytes, including all octets of header and payload.                                                                           |
| Fragment ID, flags, fragment offset | Fields used for IP fragmentation.                                                                                                                            |
| TTL                                 | Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.                                                         |
| Protocol                            | Identifier of protocol that follows in the datagram.                                                                                                         |
| Header checksum                     | Checksum of IP header. For computational purposes, this field's value is zero.                                                                               |
| Source address                      | Source IP address.                                                                                                                                           |
| Destination address                 | Destination IP address.                                                                                                                                      |

### 57.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 57-4. IPv6 header format****Table 57-8. IPv6 header fields**

| Field name          | Description                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| Version             | 4-bit IP version information. 0x6 for all IPv6 frames.                                                                    |
| Traffic class       | 8-bit field defining the traffic class.                                                                                   |
| Flow label          | 20-bit flow label identifying frames of the same flow.                                                                    |
| Payload length      | 16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.                         |
| Next header         | Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header. |
| Hop limit           | Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.   |
| Source address      | 128-bit IPv6 source address.                                                                                              |
| Destination address | 128-bit IPv6 destination address.                                                                                         |

### 57.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 57-9. ICMP header format**

|                   |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Type              |    |    |    |    |    |    |    | Code |    |    |    |    |    |    |    | Checksum |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| ICMP message data |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 57-10. IP header fields**

| Field name | Description                                    |
|------------|------------------------------------------------|
| Type       | 8-bit type information                         |
| Code       | 8-bit code that is related to the message type |

*Table continues on the next page...*

**Table 57-10. IP header fields (continued)**

| Field name | Description                                                      |
|------------|------------------------------------------------------------------|
| Checksum   | 16-bit one's complement checksum over the complete ICMP datagram |

### 57.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 57-11. UDP header format**

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15               | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source port |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Destination port |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Checksum         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 57-12. UDP header fields**

| Field name       | Description                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                          |
| Destination port | Destination application port                                                                                     |
| Length           | Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8) |
| Checksum         | Checksum over the complete datagram and some IP header information                                               |

### 57.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 57-13. TCP header format**

|                        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15               | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| Source port            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Destination port |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| Sequence number        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| Acknowledgement number |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

*Table continues on the next page...*

**Table 57-13. TCP header format (continued)**

|          |          |       |                |
|----------|----------|-------|----------------|
| Offset   | Reserved | Flags | Window         |
| Checksum |          |       | Urgent pointer |
| Options  |          |       |                |

**Table 57-14. TCP header fields**

| Field name       | Description                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                         |
| Destination port | Destination application port                                                                                    |
| Sequence number  | Transmit sequence number                                                                                        |
| Ack. number      | Receive sequence number                                                                                         |
| Offset           | Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5 |
| Flags            | URG, ACK, PSH, RST, SYN, FIN flags                                                                              |
| Window           | TCP receive window size information                                                                             |
| Checksum         | Checksum over the complete datagram (TCP header and data) and IP header information                             |
| Options          | Additional 32-bit words for protocol options                                                                    |

### 57.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 57.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 57.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 57-15 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 57-15. UDP/IP multicast domains**

| Name                | IP Address  | MAC Address mapping |
|---------------------|-------------|---------------------|
| DefaultPTPdomain    | 224.0.1.129 | 01-00-5E-00-01-81   |
| AlternatePTPdomain1 | 224.0.1.130 | 01-00-5E-00-01-82   |
| AlternatePTPdomain2 | 224.0.1.131 | 01-00-5E-00-01-83   |
| AlternatePTPdomain3 | 224.0.1.132 | 01-00-5E-00-01-84   |

**Table 57-16. UDP port numbers**

| Message type | UDP port | Note                                                        |
|--------------|----------|-------------------------------------------------------------|
| Event        | 319      | Used for SYNC and DELAY_REQUEST messages                    |
| General      | 320      | All other messages (for example, follow-up, delay-response) |

### 57.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 57-17. PTPv2 multicast domains**

| Name                | MAC address       |
|---------------------|-------------------|
| Normal messages     | 01-1B-19-00-00-00 |
| Peer delay messages | 01-80-C2-00-00-0E |

### 57.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

### 57.6.3.2.1 PTPv1 header

**Table 57-18. Common PTPv1 message header**

| Offset | Octets | Bits                          |   |   |   |   |   |   |   |
|--------|--------|-------------------------------|---|---|---|---|---|---|---|
|        |        | 7                             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0      | 2      | versionPTP = 0x0001           |   |   |   |   |   |   |   |
| 2      | 2      | versionNetwork                |   |   |   |   |   |   |   |
| 4      | 16     | subdomain                     |   |   |   |   |   |   |   |
| 20     | 1      | messageType                   |   |   |   |   |   |   |   |
| 21     | 1      | sourceCommunicationTechnology |   |   |   |   |   |   |   |
| 22     | 6      | sourceUuid                    |   |   |   |   |   |   |   |
| 28     | 2      | sourcePortId                  |   |   |   |   |   |   |   |
| 30     | 2      | sequenceId                    |   |   |   |   |   |   |   |
| 32     | 1      | control                       |   |   |   |   |   |   |   |
| 33     | 1      | 0x00                          |   |   |   |   |   |   |   |
| 34     | 2      | flags                         |   |   |   |   |   |   |   |
| 36     | 4      | reserved                      |   |   |   |   |   |   |   |

The type of message is encoded in the messageType and control fields as shown in [Table 57-19](#) :

**Table 57-19. PTPv1 message type identification**

| messageType | control | Message Name | Message         |
|-------------|---------|--------------|-----------------|
| 0x01        | 0x0     | SYNC         | Event message   |
| 0x01        | 0x1     | DELAY_REQ    | Event message   |
| 0x02        | 0x2     | FOLLOW_UP    | General message |
| 0x02        | 0x3     | DELAY_RESP   | General message |
| 0x02        | 0x4     | MANAGEMENT   | General message |
| other       | other   | —            | Reserved        |

The field sequenceId is used to non-ambiguously identify a message.

### 57.6.3.2.2 PTPv2 header

**Table 57-20. Common PTPv2 message header**

| Offset | Octets | Bits                   |   |   |   |                  |   |   |   |
|--------|--------|------------------------|---|---|---|------------------|---|---|---|
|        |        | 7                      | 6 | 5 | 4 | 3                | 2 | 1 | 0 |
| 0      | 1      | transportSpecific      |   |   |   | messageId        |   |   |   |
| 1      | 1      | reserved               |   |   |   | versionPTP = 0x2 |   |   |   |
| 2      | 2      | messageLength          |   |   |   |                  |   |   |   |
| 4      | 1      | domainNumber           |   |   |   |                  |   |   |   |
| 5      | 1      | reserved               |   |   |   |                  |   |   |   |
| 6      | 2      | flags                  |   |   |   |                  |   |   |   |
| 8      | 8      | correctionField        |   |   |   |                  |   |   |   |
| 16     | 4      | reserved               |   |   |   |                  |   |   |   |
| 20     | 10     | sourcePortIdentity     |   |   |   |                  |   |   |   |
| 30     | 2      | sequenceId             |   |   |   |                  |   |   |   |
| 32     | 1      | control                |   |   |   |                  |   |   |   |
| 33     | 1      | logMeanMessageInterval |   |   |   |                  |   |   |   |

The type of message is encoded in the field messageId as follows:

**Table 57-21. PTPv2 message type identification**

| messageId | Message name         | Message         |
|-----------|----------------------|-----------------|
| 0x0       | SYNC                 | Event message   |
| 0x1       | DELAY_REQ            | Event message   |
| 0x2       | PATH_DELAY_REQ       | Event message   |
| 0x3       | PATH_DELAY_RESP      | Event message   |
| 0x4–0x7   | —                    | Reserved        |
| 0x8       | FOLLOW_UP            | General message |
| 0x9       | DELAY_RESP           | General message |
| 0xa       | PATH_DELAY_FOLLOW_UP | General message |
| 0xb       | ANNOUNCE             | General message |
| 0xc       | SIGNALING            | General message |
| 0xd       | MANAGEMENT           | General message |

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO\_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 57-22. PTPv2 message flags field definitions**

| Bit | Name             | Description                                                                         |
|-----|------------------|-------------------------------------------------------------------------------------|
| 0   | ALTERNATE_MASTER | See IEEE 1588 Clause 17.4                                                           |

### 57.6.4 MAC receive

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

Figure 57-5. MAC receive flow

### 57.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

### 57.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 57.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 57.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

#### 57.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET $n$ \_GAUR/GALR (group address hash match) or ENET $n$ \_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET $n$ \_GAUR (msb = 1) or ENET $n$ \_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled ( $ENETn\_RCR[PROM] = 1$ ) all unicast and multicast frames are accepted regardless of  $ENETn\_GAUR/GALR$  and  $ENETn\_IAUR/IALR$  settings.

#### 57.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if  $BC\_REJ$  is cleared or  $ENETn\_RCR[PROM]$  is set. If  $PROM$  is cleared when  $ENETn\_RCR[BC\_REJ]$  is set, all broadcast frames are rejected.

**Table 57-23. Broadcast address reject programming**

| PROM | BC_REJ | Broadcast frames |
|------|--------|------------------|
| 0    | 0      | Accepted         |
| 0    | 1      | Rejected         |
| 1    | 0      | Accepted         |
| 1    | 1      | Accepted         |

#### 57.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes,  $RxBD[M]$  indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled ( $RCR[PROM] = 1$ ), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when  $BC\_REJ$  is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 57.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 57.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET $n$ \_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

#### 57.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

### 57.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if  $\text{ENETn\_RCR[FCE]}$  is cleared and are forwarded to the client interface when  $\text{ENETn\_RCR[PAUFWD]}$  is set.

### 57.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if  $\text{ENETn\_RCR[CRCFWD]}$  is cleared and  $\text{ENETn\_RCR[PADEN]}$  is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and  $\text{RxBD[CR]}$  is set.

### 57.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of  $\text{ENETn\_RCR[PADEN]}$ .

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

### 57.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if `ENETn_TCR[TFC_PAUSE]` is set with `ENETn_OPD[PAUSE_DUR]` set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if `TFC_PAUSE` is set with `PAUSE_DUR` cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 57-6. Frame transmit overview**

### 57.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC ( $\text{TxBD}[\text{TC}] = 1$ ), the user application is responsible for providing frames with a minimum length of 64 octets.

### 57.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields ( $\text{ENET}_n\text{TCR}[\text{ADDINS}] = 1$ )
- Transparently forwarded to the Ethernet line ( $\text{ENET}_n\text{TCR}[\text{ADDINS}] = 0$ )

### 57.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

#### 57.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in `ENETn_TIPG`) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

#### 57.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets `TxBD[LCE]`.

**Figure 57-7. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

### warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

### 57.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

#### 57.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

### 57.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET $n$ \_TCR[TFC\_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC\_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET $n$ \_OPD[PAUSE\_DUR].

**Figure 57-8. Pause frame generation overview**

#### Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

## 57.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

### 57.6.7.1 Sleep mode

To put the MAC in Sleep mode, set `ENETn_ECR[SLEEP]`. At the same time `ENETn_ECR[MAGICEN]` should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to `ENETn_ECR[SLEEP]` before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

### 57.6.7.2 Magic packet detection

The core is designed to detect magic packets with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in `PADDR1/2`

When a magic packet is detected, `EIR[WAKEUP]` is set and none of the statistic registers are incremented.

### 57.6.7.3 Wakeup

When a magic packet is detected, indicated by  $ENETn\_EIR[WAKEUP]$ ,  $ENETn\_ECR[SLEEP]$  should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks  $ENETn\_ECR[MAGICEN]$ , disabling magic packet detection.

## 57.6.8 IP accelerator functions

### 57.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 57-24. IPv4 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15             | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    | Protocol |    |    |    |    |    |    |    | TCP/UDP length |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 57-25. IPv6 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------------|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7           | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| TCP/UDP length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | Next header |   |   |   |   |   |   |   |

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 57.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 57.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $n$ \_TACC and ENET $n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 57-26](#).

**Table 57-26. 64-bit interface data structure with SHIFT16 enabled**

|         |         |         |         |        |        |           |           |
|---------|---------|---------|---------|--------|--------|-----------|-----------|
| 63 56   | 55 48   | 47 40   | 39 32   | 31 24  | 23 16  | 15 8      | 7 0       |
| Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 | Any value | Any value |
| Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 | Byte 7    | Byte 6    |
| ...     |         |         |         |        |        |           |           |

### 57.6.8.3.1 Receive processing

When `ENETn_RACC[SHIFT16]` is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

#### Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 57.6.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 57.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET $n$ \_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 57.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBDFRAG) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBDFragment checksum].

#### Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 57.6.8.6 IPv6 support

The following sections describe the IPv6 support.

#### 57.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing.

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

#### **57.6.8.6.2 Transmit processing**

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

### **57.6.9 Resets and stop controls**

#### **57.6.9.1 Hardware reset**

To reset the Ethernet module, set `ENETn_ECR[RESET]`.

#### **57.6.9.2 Soft reset**

When `ENETn_ECR[ETHER_EN]` is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.

- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 57.6.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 57.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER\_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 57.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### **57.6.9.4.2 Graceful receive stop (GRS)**

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set

- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

### Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

#### 57.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

## 57.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

**Figure 57-9. IEEE 1588 functions overview**

### 57.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 57.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

### Figure 57-10. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in `ENETn_ATINC`. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in `ENETn_ATPER`, defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(\text{Current} + \text{Inc} - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENETn_ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENETn_ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENETn_ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET $n$ _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

### **57.6.10.2 Transmit timestamping**

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET $n$ _ATSTMP`. `ENET $n$ _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET $n$ _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET $n$ _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

### **57.6.10.3 Receive timestamping**

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

### **57.6.10.4 Time synchronization**

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

### 57.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

#### 57.6.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

#### 57.6.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

#### NOTE

If  $TCSR_n[TMODE]$  is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when  $PINPER$ ,  $PEREN$ , and  $EN$  bits of the  $ATCR$  register are one.

#### 57.6.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSR_n[TDRE]$ . The corresponding DMA request is generated when the  $TCSR_n[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSR_n[TF]$  flag is cleared.

## 57.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

### 57.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation.

**Table 57-27. Receive FIFO thresholds definition**

| Register                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _RSFL<br>[RX_SECTION_F<br>ULL]  | <p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p> |
| ENET $n$ _RAEM<br>[RX_ALMOST_E<br>MPTY]  | <p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ENET $n$ _RAFL<br>[RX_ALMOST_F<br>ULL]   | <p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p> <p>The corresponding error status is set when the frame is delivered to the application.</p> <p>Set ENET<math>n</math>_RAFL to a minimum of 4.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ENET $n$ _RSEM<br>[RX_SECTION_E<br>MPTY] | <p>When the FIFO level reaches the ENET<math>n</math>_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.</p> <p>When the FIFO level goes below the value programmed in ENET<math>n</math>_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.</p> <p>Clearing ENET<math>n</math>_RSEM disables any pause frame generation.</p>                                                                                                                                                                                                                                                                                                    |

**Figure 57-11. Receive FIFO overview**

### 57.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation.

**Table 57-28. Transmit FIFO thresholds definition**

| Register                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _TAEM<br>[TX_ALMOST_EMPTY]  | When the FIFO level reaches the ENET $n$ _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.<br><br>Set ENET $n$ _TAEM to a minimum of 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENET $n$ _TAFL<br>[TX_ALMOST_FULL]   | When the FIFO level approaches the maximum, so that there is no more space for at least ENET $n$ _TAFL number of words, the MAC deasserts its control signal to the application.<br><br>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.<br><br>Set ENET $n$ _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion. |
| ENET $n$ _TSEM<br>[TX_SECTION_EMPTY] | When the FIFO level reaches the ENET $n$ _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.<br><br>When ENET $n$ _TSEM is 0, the signal is never deasserted.                                                                                                                                                                                                                                                                                                                                    |
| ENET $n$ _TFWR                       | When the FIFO level reaches the ENET $n$ _TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Table 57-28. Transmit FIFO thresholds definition

| Register | Description                                                                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | If a complete frame has a size smaller than the ENETn_TFWR threshold, the MAC also transmits the frame to the line.<br><br>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO. |

Figure 57-12. Transmit FIFO overview

57.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENETn\_RCR register fields found here.

Table 57-29. Loopback options

| Register field | Description                                                                                                                                                                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOOP           | Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.<br><br>In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s)) |

Figure 57-13. Loopback options

### 57.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET $_n$ \_ECR[1588EN].

#### NOTE

- The legacy buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

#### 57.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 57-33](#) contains the descriptions for each field.

Table 57-30. Legacy FEC receive buffer descriptor (RxBD)

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|----------------------------------------|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3 | 2  | 1  | 0  |

| Offset + 2 | R                                      | TO1 | W  | TO2 | L  | TC | ABC <sup>1</sup> | — | —      | — | — | — | — | — | — | — |
| Offset + 4 | Tx Data Buffer Pointer — low halfword  |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |
| Offset + 6 | Tx Data Buffer Pointer — high halfword |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |

1. This field is not supported by the uDMA.

## 57.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET<sub>n</sub>\_ECR[1588EN].

### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

### 57.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 57-33](#) contains the descriptions for each field.

**Table 57-32. Enhanced uDMA receive buffer descriptor (RxBD)**

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|----------------------------------------|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|

**Table 57-33. Receive buffer descriptor field definitions**

| Word       | Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 0 | 15–0<br>Data Length | Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.                                                                                                                                                                                                        |
| Offset + 2 | 15<br>E             | Empty. Written by the MAC (= 0) and user (= 1).<br>0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required.<br>1 The data buffer associated with this BD is empty, or reception is currently in progress.                                                                                                                                     |
| Offset + 2 | 14<br>RO1           | Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.                                                                                                                                                                                                                                                                                                                    |
| Offset + 2 | 13<br>W             | Wrap. Written by user.<br>0 The next buffer descriptor is found in the consecutive location.<br>1 The next buffer descriptor is found at the location defined in ENET <sub>n</sub> _RDSR.                                                                                                                                                                                                                                                                                         |
| Offset + 2 | 12<br>RO2           | Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.                                                                                                                                                                                                                                                                                                                    |
| Offset + 2 | 11<br>L             | Last in frame. Written by the uDMA.<br>0 The buffer is not the last in a frame.<br>1 The buffer is the last in a frame.                                                                                                                                                                                                                                                                                                                                                           |
| Offset + 2 | 10–9                | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Offset + 2 | 8<br>M              | Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set.<br>0 The frame was received because of an address recognition hit.<br>1 The frame was received because of promiscuous mode. |

**Table 57-33. Receive buffer descriptor field definitions (continued)**

| Word       | Field                                  | Description                                                                                                                                                                                                                                                                                                                             |
|------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |                                        | The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.                                                                                                                                                                                                                              |
| Offset + 2 | 7<br>BC                                | Set if the DA is broadcast (FFFF_FFFF_FFFF).                                                                                                                                                                                                                                                                                            |
| Offset + 2 | 6<br>MC                                | Set if the DA is multicast and not BC.                                                                                                                                                                                                                                                                                                  |
| Offset + 2 | 5<br>LG                                | Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.                                                                                        |
| Offset + 2 | 4<br>NO                                | Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set. |
| Offset + 2 | 3                                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 2 | 2<br>CR                                | Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.                                                                                                                                                   |
| Offset + 2 | 1<br>OV                                | Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.                                                                                         |
| Offset + 2 | 0<br>TR                                | Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.                                                                                                                                           |
| Offset + 4 | 15–0<br>Data buffer<br>pointer low     | Receive data buffer pointer, low halfword                                                                                                                                                                                                                                                                                               |
| Offset + 6 | 15–0<br>Data buffer<br>pointer<br>high | Receive data buffer pointer, high halfword<br>The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.                                                         |
| Offset + 8 | 15–13<br>VPCP                          | VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.                                   |
| Offset + 8 | 12–6                                   | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 8 | 5<br>ICE                               | IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.                    |
| Offset + 8 | 4<br>PCR                               | Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.                                                                    |
| Offset + 8 | 3                                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 8 | 2<br>VLAN                              | VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.                                                                                                                                                                         |

**Table 57-33. Receive buffer descriptor field definitions (continued)**

| Word        | Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 8  | 1<br>IPV6                | IPv6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + 8  | 0<br>FRAG                | IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Offset + A  | 15<br>ME                 | MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Offset + A  | 14–11                    | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 10<br>PE                 | PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 9<br>CE                  | Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Offset + A  | 8<br>UC                  | Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Offset + A  | 7<br>INT                 | Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Offset + A  | 6–0                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + C  | 15–0<br>Payload checksum | Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + E  | 15–11<br>Header length   | Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set. |
| Offset + E  | 10–8                     | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Offset + 2 | 11<br>L                             | Last in frame. Written by user.<br>0 The buffer is not the last in the transmit frame<br>1 The buffer is the last in the transmit frame                                                                                                                                                                    |
| Offset + 2 | 10<br>TC                            | Transmit CRC. Written by user, and valid only when L is set.<br>0 End transmission immediately after the last data byte<br>1 Transmit the CRC sequence after the last data byte<br>This field is valid only when the L field is set.                                                                       |
| Offset + 2 | 9<br>ABC                            | Append bad CRC.<br><b>Note:</b> This field is not supported by the uDMA and is ignored.                                                                                                                                                                                                                    |
| Offset + 2 | 8–0                                 | Reserved, must be cleared.                                                                                                                                                                                                                                                                                 |
| Offset + 4 | 15–0<br>Data buffer<br>pointer low  | Tx data buffer pointer, low halfword                                                                                                                                                                                                                                                                       |
| Offset + 6 | 15–0<br>Data buffer<br>pointer high | Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.                             |
| Offset + 8 | 15<br>TXE                           | Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set. |
| Offset + 8 | 14                                  | Reserved, must be cleared.                                                                                                                                                                                                                                                                                 |
| Offset + 8 | 13<br>UE                            | Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.                                                                                                                           |
| Offset + 8 | 12<br>EE                            | Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.                                                                                                             |
| Offset + 8 | 11<br>FE                            | Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.                                                                                               |
| Offset + 8 | 10<br>LCE                           | Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.                                                                                                         |

**Table 57-35. Enhanced transmit buffer descriptor field definitions (continued)**

| Word                    | Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 8              | 9<br>OE        | Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.                                                                                                                                                                                                                                 |
| Offset + 8              | 8<br>TSE       | Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.                                                                                                                                                                                                                                       |
| Offset + 8              | 7–0            | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + A              | 15             | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + A              | 14<br>INT      | Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.                                                                                                                                                                                                                                   |
| Offset + A              | 13<br>TS       | Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.                                                                                                                                                                      |
| Offset + A              | 12<br>PINS     | Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame. |
| Offset + A              | 11<br>IINS     | Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.          |
| Offset + A              | 10–0           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + C              | 15–0           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + E              | 15–0           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |

### 57.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

### 57.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 57-36. FIFO interface data structure**

|        | 63      | 56 55   | 48 47   | 40 39   | 32 31   | 24 23   | 16 15  | 8 7    | 0 |
|--------|---------|---------|---------|---------|---------|---------|--------|--------|---|
| Word 0 | Byte 7  | Byte 6  | Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 |   |
| Word 1 | Byte 15 | Byte 14 | Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 |   |
| ...    | ...     |         |         |         |         |         |        |        |   |

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 57-37. FIFO interface frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–13       | Length/type field       |
| 14–N        | Payload data            |

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 57-38. FIFO interface VLAN frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–15       | VLAN tag and info       |
| 16–17       | Length/type field       |
| 18–N        | Payload data            |

### Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

## 57.6.15.2 Data structure examples

**Figure 57-14. Normal Ethernet frame 64-bit mapping example**

**Figure 57-15. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 57.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

## 57.6.16 FIFO protection

### 57.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in Figure 57-16) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 57-16. Transmit FIFO underflow protection

### 57.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxB[OE] field for the next frame transmitted to indicate this overflow occurrence.

### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

#### 57.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxB[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 57-17. Receive FIFO overflow protection

#### 57.6.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

| Ethernet speed mode | Ethernet bus clock | Minimum ENET system clock |
|---------------------|--------------------|---------------------------|
| 10 Mbit/s           | 2.5 MHz            | 5 MHz                     |
| 100 Mbit/s          | 25.0 MHz           | 50 MHz                    |

## 57.6.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

### 57.6.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 57-39. MDIO clause 22 frame structure**

| ST | OP | PHYADR | REGADR | TA | DATA |
|----|----|--------|--------|----|------|
|----|----|--------|--------|----|------|

**Table 57-40. MDIO frame field descriptions**

| Field              | Description                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| ST<br>(2 bits)     | Start indication field, programmed with ENET $n$ _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).        |
| OP<br>(2 bits)     | Opcode defines type of operation. Programmed with ENET $n$ _MMFR[OP].<br>01 Write operation<br>10 Read operation |
| PHYADR<br>(5 bits) | Five-bit PHY device address, programmed with ENET $n$ _MMFR[PA]. Up to 32 devices can be addressed.              |

*Table continues on the next page...*

**Table 57-40. MDIO frame field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REGADR<br>(5 bits) | Five-bit register address, programmed with ENET $n$ _MMFR[RA]. Each PHY can implement up to 32 registers.                                                                                                                                                                      |
| TA<br>(2 bits)     | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| Data<br>(16 bits)  | Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY                                                                                                                                                                                                             |

### 57.6.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 57-41. MDIO clause 45 frame structure**

|    |    |       |       |    |           |
|----|----|-------|-------|----|-----------|
| ST | OP | PRTAD | DEVAD | TA | ADDR/DATA |
|----|----|-------|-------|----|-----------|

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 57-42. MDIO clause 45 frame field descriptions**

| Field | Description                                                                                                                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ST    | Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.                                                                                                |
| OP    | Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 57-43</a> for more information.<br><br>00 Address write<br>01 Write operation<br>10 Read inc. operation |

| Field     | Description                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | 11 Read operation                                                                                                                                                                                                                                                              |
| PRTAD     | The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.                                                                                                                                                   |
| DEVAD     | Device address. Up to 32 devices can be addressed (within a port).                                                                                                                                                                                                             |
| TA        | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| ADDR/DATA | 16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.                                                                                                                                                                      |

**Table 57-43. MDIO Clause 45 Transactions**

| Transaction Type | Description                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address          | A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.                                             |
| Write            | Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.                                                                                                                                             |
| Read             | Data is read from the register identified by the device-internal address.                                                                                                                                                                                        |
| Read inc.        | Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around). |

### 57.6.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 57.6.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

Figure 57-18. MDIO access overview

## 57.6.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

| Mode              | RCR[RMII_10T] | RCR[RMII_MODE] |
|-------------------|---------------|----------------|
| MII - 10 Mbit/s   | —             | 0              |
| MII - 100 Mbit/s  | —             | 0              |
| RMII - 10 Mbit/s  | 1             | 1              |
| RMII - 100 Mbit/s | 0             | 1              |

### 57.6.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

## Functional description

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

**Figure 57-19. RMII receive operation**

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 57-20. RMII receive operation with false carrier**

In RMII transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

**Figure 57-21. RMII transmit operation**

### 57.6.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 57-22. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBDF[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 57-23. MII transmit operation — errored frame**

### 57.6.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

Figure 57-24. MII transmit operation — transmission with collision

### 57.6.19.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 57-25. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 57-26. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

# Chapter 58

## Debug

### 58.1 Introduction

The debug capability on this device is based on the Arm CoreSight™ architecture and is configured on each device to provide the maximum flexibility as allowed by the restrictions of the pinout and other available resources.

**Table 58-1. Supported debug interfaces**

| Chip                 | Supported debug interfaces |                        |     |                                        |
|----------------------|----------------------------|------------------------|-----|----------------------------------------|
|                      | IEEE 1149.1 JTAG           | Serial Wire Debug(SWD) | SWO | 4-pin parallel trace port <sup>1</sup> |
| S32K116              | No <sup>2</sup>            | Yes                    | No  | No <sup>3</sup>                        |
| S32K118              | No <sup>2</sup>            | Yes                    | No  | No <sup>3</sup>                        |
| S32K142              | Yes                        | Yes                    | Yes | No                                     |
| S32K144 and S32K144W | Yes                        | Yes                    | Yes | No                                     |
| S32K146              | Yes                        | Yes                    | Yes | No                                     |
| S32K148              | Yes                        | Yes                    | Yes | Yes                                    |

1. Overrides the value of Supported Port Size Register of TPIU (at location 0x000)
2. JTAG protocol available only for Boundary Scan
3. 1 KB of MTB RAM present to store trace data

The basic Cortex debug architecture is very flexible. The following diagrams shows the topology of the core debug architecture and its components.

Figure 58-1. Cortex-M4 debug topology

**Figure 58-2. Cortex-M0+ debug topology**

The following table presents a brief description of each of the debug components.

**Table 58-2. Debug components description**

| Module                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SWJ-DP (Serial Wire and JTAG - Debug Port)        | Modified Debug Port with support for SWD, JTAG                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| AHB-AP (AMBA High-performance Bus - Access Port)  | AHB Master Interface from JTAG to debug module and SOC system memory maps                                                                                                                                                                                                                                                                                                                                                                                                                              |
| MDM-AP (Miscellaneous Debug Module - Access Port) | Provides centralized control and status registers for an external debugger to control the device.                                                                                                                                                                                                                                                                                                                                                                                                      |
| ROM Table                                         | Identifies which debug IP is available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 58.3 Debug port

The configuration of the JTAG controller, and debug port, is illustrated in the following figure.

**Figure 58-3. Modified debug port for CM4 core**

**Figure 58-4. Modified debug port for CM0+ core**

The debug port comes out of reset in standard JTAG mode and is switched into SWD mode by the following sequences. Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions.

#### NOTE

AP Abort command is not supported in S32K11x. For stalled AP transaction, reset needs to be issued.

### 58.3.1 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111\_1001\_1110\_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

#### NOTE

See the Arm documentation for the CoreSight DAP Lite for restrictions.

## 58.4 Debug port pin descriptions

After POR, all debug port pins default to their JTAG functionality and can later be reassigned to their alternate functionalities. In SWD mode, JTAG\_TDI can be configured for alternate GPIO functions.

**Table 58-6. Debug port pins**

| Pin name               | JTAG debug port |                          | SWD debug port |                                | Internal pull-up/down |
|------------------------|-----------------|--------------------------|----------------|--------------------------------|-----------------------|
|                        | Type            | Description              | Type           | Description                    |                       |
| JTAG_TMS/<br>SWD_DIO   | I/O             | JTAG Test Mode Selection | I/O            | Serial Wire Data               | Pull-up               |
| JTAG_TCLK/<br>SWD_CLK  | I               | JTAG Test Clock          | I              | Serial Wire Clock              | Pull-down             |
| JTAG_TDI               | I               | JTAG Test Data Input     | -              | -                              | Pull-up               |
| JTAG_TDO/<br>TRACE_SWO | O               | JTAG Test Data Output    | O              | Trace output over a single pin | N/C                   |

## 58.5 System TAP connection

The system JTAG controller is connected in parallel to the Arm Test Access Port (TAP) controller. The system JTAG controller Instruction Register (IR) codes overlay the Arm JTAG controller IR codes without conflict. Refer to the IR codes table for a list of the available IR codes. The output of the TAPs (TDO) are muxed based on the IR code which is selected. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP. At power on reset, Arm's IDCODE (IR = 1110b) is selected.

### 58.5.1 IR codes

**Table 58-7. JTAG instructions**

| Instruction         | Code[3:0] | Instruction summary                                                                                           |
|---------------------|-----------|---------------------------------------------------------------------------------------------------------------|
| IDCODE <sup>1</sup> | 0000      | Selects device identification register for shift                                                              |
| SAMPLE/PRELOAD      | 0010      | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation |
| SAMPLE              | 0011      | Selects boundary scan register for shifting and sampling without disturbing functional operation              |
| EXTEST              | 0100      | Selects boundary scan register while applying preloaded values to output pins and asserting functional reset  |

*Table continues on the next page...*

**Table 58-7. JTAG instructions (continued)**

| Instruction                       | Code[3:0]              | Instruction summary                                                                                                                         |
|-----------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| HIGHZ                             | 1001                   | Selects bypass register while three-stating all output pins and asserting functional reset                                                  |
| CLAMP                             | 1100                   | Selects bypass register while applying preloaded values to output pins and asserting functional reset                                       |
| Arm_IDCODE <sup>2</sup>           | 1110                   | Arm JTAG-DP Instruction                                                                                                                     |
| BYPASS                            | 1111                   | Selects bypass register for data operations                                                                                                 |
| Factory debug reserved            | 0101, 0110, 0111, 1101 | Intended for factory debug only                                                                                                             |
| Arm JTAG-DP Reserved <sup>2</sup> | 1000, 1010, 1011, 1110 | These instructions will go the Arm JTAG-DP controller. Please see the Arm JTAG-DP documentation for more information on these instructions. |
| Reserved <sup>3</sup>             | All other opcodes      | Decoded to select bypass register                                                                                                           |

1. Device IDCODE can only be read in JTAG mode.
2. Reserved for S32K11x variants
3. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

## 58.6 MDM-AP status and control registers

Through the Arm Debug Access Port (DAP), the debugger has access to the status and control elements, implemented as registers on the DAP bus as shown in [Figure 58-5](#). These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also allow the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

These DAP control and status registers are not memory mapped within the system memory map and are only accessible via the DAP using JTAG or SWD. The MDM-AP is accessible as Debug Access Port 1 with the available registers shown in the table below.

**Table 58-8. MDM-AP register summary**

| Address     | Register | Description                                                                     |
|-------------|----------|---------------------------------------------------------------------------------|
| 0x0100_0000 | Status   | See <a href="#">MDM-AP Status Register</a>                                      |
| 0x0100_0004 | Control  | See <a href="#">MDM-AP Control Register</a>                                     |
| 0x0100_00FC | ID       | Read-only identification register that always reads as 0x001C_0000 <sup>1</sup> |

1. This value is applicable only for S32K14x devices.

Figure 58-5. MDM AP addressing

## 58.6.1 MDM-AP Control Register

Table 58-9. MDM-AP Control Register assignments

| Bit | Name                                | Command available in secure mode? | Description                                                                                                                                                                                                                                                                   |
|-----|-------------------------------------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Flash memory mass erase in progress | Yes                               | Set to cause mass erase. Cleared by hardware after mass erase operation completes.<br><br>When mass erase is disabled (via MEEN and SEC settings), the erase request does not occur and the Flash Mass Erase in Progress bit continues to assert until the next system reset. |
| 1   | Debug disable                       | No                                | Set to disable debug. Clear to allow debug operation.                                                                                                                                                                                                                         |
| 2   | Debug request                       | No                                | Set to force the core to halt.                                                                                                                                                                                                                                                |

## 58.6.2 MDM-AP Status Register

**Table 58-10. MDM-AP Status Register assignments**

| Bit | Name                                | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Flash memory mass erase acknowledge | This bit is cleared on debug reset. The bit is also cleared at the launch of a mass erase command due to writing the Mass Erase in Progress bit in the MDM AP Control Register. This bit is set after the flash memory control logic has started the mass erase operation.<br><br>When mass erase is disabled (via MEEN and SEC settings), an erase request due to setting the bit is not acknowledged. |
| 1   | Flash memory ready                  | Indicates flash memory has been initialized and the debugger can be configured even if the system is continuing to be held in reset via the debugger.                                                                                                                                                                                                                                                   |
| 2   | System security                     | Indicates the security state. When secure, the debugger does not have access to the system bus or any memory mapped peripherals. This bit indicates when the part is locked and no system bus access is possible.                                                                                                                                                                                       |
| 3   | System reset                        | Indicates the system reset state.<br><br>0: System is in reset<br><br>1: System is not in reset                                                                                                                                                                                                                                                                                                         |

| 5       | Mass erase enable          | Indicates whether the MCU can be mass erased<br>0: Mass erase is disabled<br>1: Mass erase is enabled                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 6       | Backdoor access key enable | Indicates whether the MCU has the backdoor access key enabled. See the FTFE_FSEC[KEYEN] bit for more information.<br>0: Disabled<br>1: Enabled                                                                                                                                                                                                                                                                                                                                                                                 |
| 7       | LP enabled                 | Decode of LPLLSM control bits to indicate that VLPS is the selected power mode the next time the Arm core enters Deep Sleep.<br>0: Low Power Stop Mode is not enabled<br>1: Low Power Stop Mode is enabled<br>Usage is intended for debug operation in which Run to VLPS is attempted. Per debug definition, the system actually enters the Stop state. A debugger should interpret deep sleep indication (with SLEEPDEEP and SLEEPING asserted) in conjunction with this bit asserted as the debugger-VLPS status indication. |
| 8       | Very low power mode        | Indicates current power mode is VLPx. This bit is not 'sticky' and should always represent whether VLPx is enabled or not.<br>This bit is used by the debugger to throttle JTAG TCK frequency up/down.                                                                                                                                                                                                                                                                                                                         |
| 9 – 10  | Reserved                   | Always reads as 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 11 – 15 | Reserved for future use    | Always read as 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 16      | Core halted                | Indicates the core has entered debug halt mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 17      | Core SLEEPDEEP             | Indicates the core has entered a low power mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 18      | Core SLEEPING              | SLEEPING==1 and SLEEPDEEP==1 indicates stop or VLPS mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 19 – 31 | Reserved for future use    | Always reads as 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## 58.7 Debug resets

The debug system receives the following sources of reset:

- Debug reset (CDBGIRSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to reset the debug logic <sup>1</sup>
- System POR reset

Conversely, the debug system is capable of generating system reset using the following mechanism:

1. This reset is not available in S32K11x variants.

- A system reset in the DAP control register which allows the debugger to hold the system in reset
- SYSRESETREQ bit in the NVIC application interrupt and reset control register

## 58.8 AHB-AP

AHB-AP provides the debugger access to all memory and registers in the system, including processor registers through the NVIC. System access is independent of the processor status. AHB-AP does not perform back-to-back transactions on the bus, so all transactions are non-sequential. AHB-AP can perform unaligned and bit-band transactions. AHB-AP transactions bypass the FPB, so the FPB cannot remap AHB-AP transactions. SWJ/SW-DP-initiated transaction aborts drive an AHB-AP-supported sideband signal called HABORT. This signal is driven into the Bus Matrix, which resets the Bus Matrix state, so that AHB-AP can access the Private Peripheral Bus for last ditch debugging such as read/stop/reset the core. AHB-AP transactions are little-endian.

The MPU includes default settings and protections for the Region Descriptor 0 (RGD0) such that the Debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

For a short period at the start of a system reset event, the system security status is being determined and debugger access to all AHB-AP transactions is blocked. The MDM-AP Status register is accessible and can be monitored to determine when this initial period is completed. After this initial period, if system reset is held via assertion of the RESET\_b pin, the debugger has access via the bus matrix to the private peripheral bus to configure the debug IP even while system reset is asserted. While in system reset, access to other memory and register resources, accessed over the crossbar switch, is blocked.

## 58.9 ITM

The Instrumentation Trace Macrocell (ITM) is an application-driven trace source that supports printf style debugging to trace operating system and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace: Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace: The DWT generates these packets, and the ITM emits them.

3. Time stamping: Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The counter is clocked either by the Cortex-M4 clock or by the bit clock rate of the Serial Wire Viewer (SWV) output.
4. Global system timestamping: Timestamps can optionally be generated using a system-wide 48-bit count value.

## 58.10 Core trace connectivity

Following table provides Core trace connectivity across S32K1xx devices.

**Table 58-11. Core Trace Connectivity**

| Chip                                    | Feature                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------|
| S32K116, S32K118                        | Trace data generated by the CM0+ core can be stored in MTB RAM.                         |
| S32K142, S32K144, S32K144W, and S32K146 | DWT and ITM trace data can be traced out only through SWO interface.                    |
| S32K148                                 | DWT, ETM and ITM trace data can be traced out through SWO or 4 pin parallel trace port. |

## 58.11 TPIU

The TPIU is a trace data drain that acts as a bridge between the on-chip trace data to a data stream that is captured by a *Trace Port Analyzer* (TPA).

**Table 58-12. S32K14x TPIU**

| Chip                                    | Feature                                                                                                                                                                   |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S32K16, 118                             | Not present                                                                                                                                                               |
| S32K142, S32K144, S32K144W, and S32K146 | The TPIU in the device supports a limited subset of the full TPIU functionality (only SWO mode), to minimize gatecount for a simple debug solution.                       |
| S32K148                                 | For applications which require high trace bandwidth, 4 pin trace interface can be used.<br><br>SWO mode can be used only in SWD mode as it uses the same pin as JTAG TDO. |

Maximum trace clock for SWO is 20 MHz. Maximum trace clock for 4-pin trace interface mapped to:

- Fast pads is 80 MHz
- Slow pads is 20 MHz

This can be configured through [System Clock Divider Register 4 \(CLKDIV4\)](#) register.

## 58.12 DWT

The DWT provides debug functionality. It contains four comparators, each of which can be configured as a hardware watchpoint, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT\_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT\_COMP1, can also be used as a data comparator. DWT also contains counters for:

- Clock cycles (CYCCNT)
- Folded instructions
- Load store unit (LSU) operations
- Sleep cycles
- CPI (all instruction cycles except for the first cycle)
- Interrupt overhead

An event is emitted each time a counter overflows.

The DWT can be configured to emit PC samples at defined intervals, and to emit interrupt event information.

### NOTE

The MTB\_DWT\_FCT[FUNCTION]=0100 (i.e. Instruction Fetch) is only valid when DATAVMATCH=0.

## 58.13 MTB

The Micro Trace Buffer (MTB) provides a simple execution trace capability for the Cortex-M0+ processor. When enabled, the MTB records changes in program flow reported by the Cortex-M0+ processor, via the execution trace interface, into a configurable region of the MTB SRAM. Subsequently, an off-chip debugger may extract the trace information, which would allow reconstruction of an instruction flow trace. The MTB does not include any form of load/store data trace capability or tracing of any other information. In addition to providing the trace capability, the MTB also operates as a simple AHB-Lite SRAM controller. The system bus masters, including the processor, have read/write access to all of the SRAM via the AHB-Lite interface, allowing the memory to be also used to store program and data information. The MTB simultaneously stores the trace information into an attached SRAM and allows bus masters to access the memory. The MTB ensures that trace information write accesses to the SRAM take priority over accesses from the AHB-Lite interface.

The MTB includes trace control registers for configuring and triggering the MTB functions. The MTB also supports triggering via TSTART and TSTOP control functions in the MTB DWT module.

## 58.14 Debug in low-power modes

In low-power modes, in which the debug modules are kept static or powered off, the debugger cannot gather any debug data for the duration of the low-power mode. In the case that the debugger is held static, the debug port returns to full functionality as soon as the low-power mode exits and the system returns to a state with active debug. In the case that the debugger logic is powered off, the debugger is reset upon recovery and must be reconfigured after the low power mode is exited.

Debug Power Up and System Power Up signals from the debug port are monitored by the power mode entry logic as indications that a debugger is active. These signals can be changed in RUN and VLPR. If the debug signal is active and the system attempts to enter stop or VLPS, FCLK continues to run to support core register access. In these modes in which FCLK is left active, the debug modules have access to core registers but not to system memory resources accessed via the crossbar switch.

With debug enabled, transitions from Run directly to VLPS are not allowed and result in the system entering Stop mode instead. Status bits within the MDM-AP Status register can be evaluated to determine this pseudo-VLPS state. Note that with debug enabled, transitions from Run→VLPR→VLPS are still possible but also result in the system entering Stop mode instead.

### 58.14.1 Debug module state in low-power modes

The following table shows the state of the debug modules in low power modes. These terms are used:

- FF = Full functionality. In VLPR the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.
- OFF = Modules are powered off; module is in reset state upon wakeup.

**Table 58-13. Debug module state in low-power modes**

| Module     | STOP <sup>1</sup> | VLPR | VLPS |
|------------|-------------------|------|------|
| Debug Port | FF                | FF   | OFF  |
| AHB-AP     | FF                | FF   | OFF  |

*Table continues on the next page...*

**Table 58-13. Debug module state in low-power modes (continued)**

| Module | STOP <sup>1</sup> | VLPR | VLPS |
|--------|-------------------|------|------|
| ITM    | FF                | FF   | OFF  |
| TPIU   | FF                | FF   | OFF  |
| DWT    | FF                | FF   | OFF  |
| ETM    | FF                | FF   | OFF  |
| MTB    | FF                | FF   | OFF  |

1. Debugger state in STOP1 and STOP2 is same as in STOP.

## 58.15 Debug and security

When security is enabled (FSEC[SEC] != 10), the debug port capabilities are limited to prevent exploitation of secure data. In the secure state, the debugger still has access to the MDM-AP Status Register and can determine the current security state of the device. In the case of a secure device, the debugger also has the capability of performing a mass erase operation via writes to the MDM-AP Control Register. In the case of a secure device that has mass erase disabled (FSEC[MEEN] = 10), attempts to mass erase via the debug interface are blocked.

## Chapter 59

# JTAG Controller (JTAGC)

### 59.1 Chip-specific JTAGC information

In the JTAGC's [Device identification register](#), the value of the Part Identification Number (PIN) field varies across the products in the S32K1xx series. The following table provides the PIN value for each product.

**Table 59-1. JTAG ID register's PIN value**

| Chip     | PIN value    |
|----------|--------------|
| S32K116  | 0b0100110100 |
| S32K118  | 0b0100110000 |
| S32K142  | 0b0100111000 |
| S32K144  | 0b0100111101 |
| S32K144W | 0b0101010100 |
| S32K146  | 0b0101000100 |
| S32K148  | 0b0101010000 |

### 59.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

## 59.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information as well as [Register description](#) for more information about the JTAGC registers.

**Figure 59-1. JTAG (IEEE 1149.1) block diagram**

## 59.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - Four pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see [JTAGC block instructions](#) for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

## 59.2.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

### 59.2.3.1 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

### 59.2.3.2 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE, and SAMPLE/PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 59.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 59.3 External signal description

The JTAGC consists of a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 59-2. JTAG signal properties**

| Name | I/O    | Function         | Reset state         |
|------|--------|------------------|---------------------|
| TCK  | Input  | Test clock       | Weak pulldown       |
| TDI  | Input  | Test data in     | Weak pullup         |
| TDO  | Output | Test data out    | High Z <sup>1</sup> |
| TMS  | Input  | Test mode select | Weak pullup         |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 59.3.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 59.3.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 59.3.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 59.3.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 59.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 59.4.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        | 3                | 2 | 1 | 0 |
|--------|------------------|---|---|---|
| R      | 0                | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |
| Reset: | 0                | 0 | 0 | 1 |

**Figure 59-2. Instruction register**

### 59.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 59.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

|       |                            |    |    |    |                            |    |    |    |    |    |    |    |                            |    |    |    |
|-------|----------------------------|----|----|----|----------------------------|----|----|----|----|----|----|----|----------------------------|----|----|----|
|       | 31                         | 30 | 29 | 28 | 27                         | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19                         | 18 | 17 | 16 |

| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1. |

#### 59.4.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

### 59.5 Functional description

This section explains the JTAGC functional description.

#### 59.5.1 JTAGC reset configuration

When in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

#### 59.5.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

**Figure 59-3. Shifting data through a register**

### 59.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 59-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 59.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 59.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

### 59.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 59-4. 4-bit JTAG instructions**

| Instruction            | Code[3:0] | Instruction summary                                                                                                                                     |

### 59.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

### 59.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

### 59.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins, and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

### 59.5.4.4 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

### 59.5.4.5 ENABLE\_SOC\_DATA1 instruction

The ENABLE\_SOC\_DATA1 instruction captures SoC data and selects the SOC\_DATA register for connection as the shift path between TDI and TDO.

### 59.5.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

### 59.5.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single

bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### 59.5.4.8 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the system logic operates normally.

### 59.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

## 59.6 Initialization/application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS.
2. Load the appropriate instruction for the test or action to be performed.

# Appendix A

# Appendix B

## Release Notes for Revision 14

### B.1 General changes

- In [Fast IRC Control Status Register \(SCG\\_FIRCCSR\)](#), changed the bit FIRCERR to Reserved.

### B.2 About This Manual changes

- In [Audience](#), removed note 'Technical information for S32K14xW ... '

### B.3 Introduction changes

- No substantial content changes

### B.4 Memory map changes

- No substantial content changes

### B.5 Signal multiplexing changes

- No substantial content changes

## B.6 Security Overview changes

- No substantial content changes

## B.7 Safety Overview changes

- No substantial content changes

## B.8 CM0+ Overview changes

- No substantial content changes

## B.9 CM4 Overview changes

- No substantial content changes

## B.10 MTB changes

- No substantial content changes

## B.11 MCM changes

### B.11.1 Chip-specific MCM information changes

- No substantial content changes

### B.11.2 MCM changes

- No substantial content changes

## B.12 SIM changes

### B.12.1 Chip-specific SIM information changes

- In [Miscellaneous control register 0 \(MISCTRL0\)](#), changed MGRAM to Internal scratch RAM (This is an internal RAM, accessible only within flash and not by any master) and changed MGATE to flash internal.

### B.12.2 SIM changes

- Updated description of SDID register

## B.13 PORT changes

### B.13.1 Chip-specific PORT information changes

- No substantial content changes

### B.13.2 Port Control and Interrupts (PORT) changes

- No substantial content changes

## B.14 GPIO changes

### B.14.1 Chip-specific GPIO information changes

- No substantial content changes

### B.14.2 GPIO module changes

- No substantial content changes

## B.15 AXBS-Lite changes

### B.15.1 Chip-specific AXBS-Lite information changes

- No substantial content changes

### B.15.2 AXBS\_Lite module changes

- No substantial content changes

## B.16 MPU changes

### B.16.1 Chip-specific MPU information changes

- In [Chip-specific MPU information](#), added note "RGD0\_WORD2[M1PE] bit field is not used in S32K116 and S31K118".

### B.16.2 MPU module changes

- No substantial content changes

## B.17 AIPS-Lite changes

### B.17.1 Chip-specific AIPS information changes

- No substantial content changes

### B.17.2 AIPS\_Lite module changes

- No substantial content changes

## B.18 DMAMUX changes

### B.18.1 Chip-specific DMAMUX information changes

- No substantial content changes

### B.18.2 DMAMUX module changes

- No substantial content changes

## B.19 eDMA changes

### B.19.1 Chip-specific eDMA information changes

- No substantial content changes

### B.19.2 eDMA2 module changes

- Marked CR[VERSION] field reserved.
- In [eDMA basic data flow](#) updated statement 'eDMA engine address path channel x or y registers' to 'eDMA engine's internal register file' and statement '...load it into the address path channel x or y registers' to '.... load it into the internal register file'.
- In [eDMA initialization](#) updated statement 'As the TCD is read, the first transfer is initiated on the internal' to 'As the TCD is read, the first transfer is initiated on the system bus'.
- In [Channel linking](#) updated value of TCDn\_CSR[MAJOR\_LINKCH] from 0x7 to 0x3, updated 'TCD12\_CSR[START] bit' to 'TCD2\_CSR[START] bit', and 'TCD7\_CSR[START] bit' to 'TCD3\_CSR[START] bit'
- Updated the bit field value description of field [EDBG](#).
- Re-structured and re-aligned the sections outline.
- Replaced section "Introductin" with "Overview".
- Replaced section heading "eDMA system block diagram" with "Block diagram".
- Added Clocks section under Functional description.
- In [Table 18-2](#) modified the first bullet list of address path cloumn.
- Editorial changes
- Removed section 'Clocks'.
- Removed statement 'otherwise, a configuration error is reported' from TCDn\_BITER\_ELINKYES and TCDn\_BITER\_ELINKNO.

## B.20 TRGMUX changes

### B.20.1 Chip-specific TRGMUX information changes

- No substantial content changes

### B.20.2 TRGMUX module changes

- No substantial content changes

## B.21 EWM changes

### B.21.1 Chip-specific EWM information changes

- No substantial content changes

### B.21.2 EWM module changes

- No substantial content changes

## B.22 EIM changes

### B.22.1 Chip-specific EIM information changes

- No substantial content changes

### B.22.2 EIM changes

- No substantial content changes

## B.23 ERM changes

### B.23.1 Chip-specific ERM information changes

- No substantial content changes

### B.23.2 ERM module changes

- No substantial content changes

## B.24 WDOG changes

### B.24.1 Chip-specific WDOG information changes

- No substantial content changes

### B.24.2 WDOG module changes

- No substantial content changes

## B.25 CRC module changes

- Removed the specific mode names from the section [Low-power modes \(Stop\)](#).
- Added the section [Use cases](#).
- Editorial changes throughout.
- Editorial changes throughout.
- Added the note "Write access to the register.....if a transfer error occurs", to [Memory map and register descriptions](#).

## B.26 Reset and Boot changes

- No substantial content changes

## **B.27 RCM changes**

### **B.27.1 Chip-specific RCM information changes**

- No substantial content changes

### **B.27.2 RCM changes**

- No substantial content changes

## **B.28 Clock Distribution changes**

- No substantial content changes

## **B.29 SCG changes**

### **B.29.1 Chip-specific SCG information changes**

### **B.29.2 SCG changes**

- No substantial content changes

## **B.30 PCC changes**

### **B.30.1 Chip-specific PCC information changes**

- No substantial content changes

## B.30.2 PCC module changes

- No substantial content changes

## B.31 CMU changes

### B.31.1 CMU changes

- No substantial content changes

### B.31.2 CMU\_FC module changes

- No substantial content changes

## B.32 Memories and memory interfaces changes

- [SRAM sizes](#)
  - For the details on SRAM size added reference to datasheet

## B.33 PRAMC changes

- No substantial content changes

## B.34 LMEM changes

### B.34.1 Chip-specific LMEM information changes

- No substantial content changes

## **B.34.2 LMEM module changes**

- No substantial content changes

## **B.35 MSCM changes**

### **B.35.1 Chip-specific MSCM information changes**

- No substantial content changes

### **B.35.2 MSCM changes**

- No substantial content changes

## **B.36 FMC changes**

### **B.36.1 Chip-specific FMC changes**

- No substantial content changes

### **B.36.2 FMC changes**

- No substantial content changes

## **B.37 FTFC changes**

### **B.37.1 Chip-specific FTFC information changes**

## B.37.2 FTFC changes

- No substantial content changes

## B.38 FTFM changes

- Update flash command timing values.

## B.39 QSPI changes

### B.39.1 Chip-specific QSPI information changes

- No substantial content changes

### B.39.2 QuadSPI changes

- No substantial content changes

## B.40 Power Management changes

- In [Table 39-4](#), for 12-bit ADC changed the VLPR from OFF to FF (Only SIRC as a source).
- In [Table 39-4](#), added row for SYSTICK module.

## B.41 SMC changes

- No substantial content changes

## B.42 PMC changes

### B.42.1 Chip-specific PMC changes

- No substantial content changes

### B.42.2 PMC module changes

- In [Low Voltage Reset \(LVR\) Operation](#), added a note.

## B.43 ADC Configuration changes

- In [Table 43-1](#) and [Table 43-2](#) added information for S32K142W.

## B.44 ADC changes

### B.44.1 Chip-specific ADC information changes

- No substantial content changes

### B.44.2 ADC module changes

- No substantial content changes

## B.45 CMP changes

### B.45.1 Chip-specific CMP changes

- In section [Table 45-1](#), added S32K142W information.

## B.45.2 CMP changes

- Minor correction in C1[INNSEL]: "... selected for the minus input of the comparator".

## B.46 PDB changes

### B.46.1 Chip-specific PDB information changes

- In [Table 46-1](#), added S32K142W information.

### B.46.2 PDB changes

- No substantial content changes

## B.47 FTM changes

### B.47.1 Chip-specific FTM information changes

- Added [FTM fixed frequency clock](#) .

### B.47.2 FTM module changes

- No substantial content changes

## B.48 LPIT changes

### B.48.1 Chip-specific LPIT information changes

- No substantial content changes

## B.48.2 LPIT module changes

- No substantial content changes

## B.49 LPTMR changes

### B.49.1 Chip-specific LPTMR information changes

- No substantial content changes

### B.49.2 LPTMR module changes

- No substantial content changes

## B.50 RTC changes

### B.50.1 Chip-specific RTC changes

- No substantial content changes

### B.50.2 RTC module changes

- No substantial content changes

## B.51 LPSPI changes

### B.51.1 Chip-specific LPSPI information changes

- No substantial content changes

## **B.51.2 LPSPI module changes**

- No substantial content changes

## **B.52 LPI2C changes**

### **B.52.1 Chip-specific LPI2C information changes**

- No substantial content changes

### **B.52.2 LPI2C module changes**

- No substantial content changes

## **B.53 LPUART changes**

### **B.53.1 Chip-specific LPUART information changes**

- No substantial content changes

### **B.53.2 LPUART module changes**

- No substantial content changes

## **B.54 FlexIO changes**

### **B.54.1 Chip-specific FlexIO changes**

- No substantial content changes

## B.54.2 FlexIO module changes

- No substantial content changes

## B.55 FlexCAN changes

### B.55.1 Chip-specific FlexCAN information changes

- No substantial content changes

### B.55.2 FlexCAN module changes

- In [FlexCAN initialization sequence](#) changed "The FlexCAN module may be reset in three ways" to "You can reset FlexCAN in the following ways."
- In [Error and Status 1 Register \(ESR1\)](#), added the following text to all read-only error-flag fields: "After a read operation, the field's value clears to 0."
- Made editorial changes.
- Made editorial changes.
- Removed Introduction section.
- Added the following sections:
  - [Block diagram](#)
  - [Clocks](#)
  - [Reset](#)
- In [Features](#), changed the heading to Features.
- Moved [Modes of operation](#) under "Functional Description".
- Moved [Modes of operation details](#) under "Modes of operation".
- Moved [Clock domains and restrictions](#) under "Clocks".
- In [FlexCAN initialization sequence](#), removed the reset related content.
- In [Modes of operation](#) under CAN FD Active mode replaced sentence "FD Protocol and CAN 2.0 Protocol 2.0" with "FD, Standard (2.0) and 2.0B Protocol".
- In [Clock domains and restrictions](#), removed the texts "and is derived from the peripheral clock" and "and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus" as internal.
- In [Error and Status 1 Register \(ESR1\)](#), added MCR[WRNEN] in the text "CPU must clear this flag before disabling MCR[WRNEN]".
- In [Error and Status 1 Register \(ESR1\)](#), added note "Reading Host can clear these field".
- In [Control 1 Register \(CTRL1\)](#), moved the text "This bit can be written in Freeze mode only because it is blocked by hardware in other modes" after the notes.
- In [Bus interface](#), added table "Access permissions".
- In [Clocks](#), changed the text from "Clock Controller Module (CCM)" to "chip clocking chapter".

## B.56 SAI changes

### B.56.1 Chip-specific SAI changes

- No substantial content changes

### B.56.2 SAI module changes

- No substantial content changes

## B.57 ENETchanges

### B.57.1 Chip-specific ENET changes

- No substantial content changes

### B.57.2 ENET module changes

- No substantial content changes

## B.58 Debug changes

- In [MDM-AP status and control registers](#), added footnote "This value is applicable only for S32K14x devices".

## B.59 JTAGC changes

### B.59.1 Chip-specific JTAGC information changes

- No substantial content changes

## B.59.2 JTAGC module changes

- No substantial content changes

Information in this document is provided solely to enable system and software implementers to use NXP products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits based on the information in this document. NXP reserves the right to make changes without further notice to any products herein.

NXP makes no warranty, representation, or guarantee regarding the suitability of its products for any particular purpose, nor does NXP assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in NXP data sheets and/or specifications can and do vary in different applications, and actual performance may vary over time. All operating parameters, including "typicals," must be validated for each customer application by customer's technical experts. NXP does not convey any license under its patent rights nor the rights of others. NXP sells products pursuant to standard terms and conditions of sale, which can be found at the following address: [nxp.com/SalesTermsandConditions](http://nxp.com/SalesTermsandConditions).

While NXP has implemented advanced security features, all products may be subject to unidentified vulnerabilities. Customers are responsible for the design and operation of their applications and products to reduce the effect of these vulnerabilities on customer's applications and products, and NXP accepts no liability for any vulnerability that is discovered. Customers should implement appropriate design and operating safeguards to minimize the risks associated with their applications and products.
