## Introduction

This addendum describes corrections or updates to the S32K1xx Reference Manual. The currently-available version of the S32K1xx Reference Manual is Revision 14. In the table below, the page numbers in the Location column are relative to that version.

Navigation tip: When navigating this PDF file using the hyperlinks, pressing the ALT and "left arrow" keys simultaneously will return you to the previously viewed page.

## Chapter 2

# System OSC Divide Register (SCG\_SOSCDIV)

The SCG\_SOSCDIV register provides the control of clock trees which can be used to provide optional peripheral functional clocks, or alternative module clocks. Each clock tree has optional dividers of the input SOSC clock. Changes to SOSCDIV should be done when System OSC is disabled to prevent glitches to output divided clock.

## Chapter 3

# Program Partition command

The Program Partition command prepares the FlexNVM block for use as data flash, emulated EEPROM backup, or a combination of both and initializes the FlexRAM. The Program Partition command must not be launched from flash memory, since flash memory resources are not accessible during Program Partition command execution. Changes related to execution of the Program Partition command take effect after the next reset.

The Program Partition command is expected to be run for fresh parts before other FTFC and CSEc commands are launched.

### CAUTION

While different partitions of the FlexNVM are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM Partition Code choices affect the endurance and data retention characteristics of the device.

Interrupting a Program Partition operation (due to power loss, reset, supplies out of specified operational ranges, or any other reasons) can leave the partition codes in an indeterminate state. The user must take appropriate counter measures to prevent data loss in case of an interrupted Program Partition operation.

**Table 2. Program Partition command FCCOB requirements**

| FCCOB Number | FCCOB Contents [7:0]                                                                                                                                                                                                                                         |

Table 3. CSEc/SHE key size

| FCCOB1 [1:0] | Number of Flash Keys ({MASTER_ECU_KEY, BOOT_MAC_KEY, BOOT_MAC, KEY_<n>}) | Number of Bytes (subtracts from the total EEERAM space) |
|--------------|--------------------------------------------------------------------------|---------------------------------------------------------|
| 2'b00        | Zero                                                                     | 0                                                       |
| 2'b01        | 1 to 5 keys                                                              | 128 Bytes                                               |
| 2'b10        | 1 to 10 keys                                                             | 256 Bytes                                               |
| 2'b11        | 1 to 20 keys                                                             | 512 Bytes                                               |

For non-CSEc enabled parts, the number of Flash Keys must be configured as 2'b00 (no keys). The BKRON value in FCCOB6 is ignored and left unprogrammed/erased (1b1) if the CSEc Key Size is 0.

For CSEc enabled parts, the number of Flash Keys is user configurable, but the space will assume that the MASTER\_ECU\_KEY, BOOT\_MAC\_KEY and BOOT\_MAC are there (if any keys are enabled), and thus will occupy 3 key slots of the available 20 key slot space. This results in leaving key slots for a range of 1 to 17 User Key\_<n> keys.

For non-CSEc enabled parts the key allocation must be set to Zero keys (2'b00), otherwise the command will return an error.

#### NOTE

For CSEc enabled parts, once Flash Keys are allocated (regardless of being initialized or not), the SHE spec requirement of not erasing Flash Keys without authentication will apply. This will mean Authentication (DBG\_CHAL & DBG\_AUTH) commands must be run and pass (removing all flash keys) before erase of the DFlash (all Flash Keys are backed up in emulated EEPROM in DFlash). Thus Erase All Blocks and Erase All Blocks Unsecure will not work, nor will Erase Flash Block or Sector IF the selected Block/Sector includes the DFlash where the keys are stored. Additionally if any Flash Keys are write protected, they can't be erased/removed, thus the DFlash can't be erased and the Authentication process will not pass.

Table 4. Security Flag Extension (SFE)

| SFE         | Results                                       |
|-------------|-----------------------------------------------|
| SFE == 0x01 | Flash Key 'Verify Only' attribute enabled     |
| SFE == 0x00 | Flash Key 'Verify Only' attribute not enabled |

The FCCOB[2] field for the enhanced Security Flag Extension (SFE) is in a 8-bit field, but only bit [0] is used (bits [7:1] are ignored). This feature is an extension to the SHE specification. For standard SHE usage model, the user should configure this as 'not enabled' (SFE == 0x00). This addition is to add capability to flag a key as 'VERIFY\_ONLY'. That is, the user can configure SFE == 0x01 and then use the LOAD\_KEY command to add a new attribute to the key which would tell the GENERATE\_MAC command that the key is to be used only by the VERIFY\_MAC command (by configuring SFE as 'enabled' and then using LOAD\_KEY to set the new VERIFY\_ONLY attribute on that key).

The VERIFY\_ONLY attribute has no effect if the KEY\_USAGE attribute is '0'.

See the CMD\_LOAD\_KEY command for more information on the new attribute.

When FCCOB1[7] equals 0x1, the content of FCCOB7[6:0] sets the minimum MAC length for VERIFY\_MAC commands for both data and pointer methods (FCCOB7[7] is ignored). A value of 0x0 is interpreted as 128-bits, while values 0x1 to 0x7F are directly interpreted as 1 to 127-bits.

When FCCOB1[7] equals 0x0, the value of FCCOB7 is ignored, instead using 1-bit as the minimum MAC length for VERIFY\_MAC commands.

Table 5. Valid emulated EEPROM data set size codes : 2 KB FlexRAM configurations

| EEPROM Data Set Size Code (FCCOB4) <sup>1</sup> | EEPROM Data Set Size (Bytes) |
|-------------------------------------------------|------------------------------|
| EEESIZE (FCCOB4[3:0])                           |                              |
| 0xF                                             | 0 <sup>2</sup>               |
| 0x3                                             | 2k                           |

1. FCCOB4[7:4] = 0000

2. EEPROM Data Set Size must be set to 0 Bytes when the FlexNVM Partition Code is set for no EEPROM.

Table 6. Valid emulated EEPROM data set size codes : 4 KB FlexRAM configurations

| EEPROM Data Set Size Code (FCCOB4) <sup>1</sup> | EEPROM Data Set Size (Bytes) |
|-------------------------------------------------|------------------------------|
| EEESIZE (FCCOB4[3:0])                           |                              |

1. FCCOB5[7:4] = 0000

**NOTE**

For the 2M configuration (where DFlash is implemented in multiple blocks) the FlexNVM may only be configured into: all Data flash, or 64 KB emulated EEPROM backup with the remainder left as Data Flash. Thus there are only three valid values for DEPART (FCCOB5[3:0]) : either 4'b0100 (64 KB emulated EEPROM, remainder is DFlash) or 4'b0000, 4'b1111 (0 KB emulated EEPROM/all DFlash).

**Table 9. Valid FlexNVM partition codes: 2 MB configurations**

| FlexNVM Partition Code DEPART (FCCOB5[3:0]) <sup>1</sup> | Data flash Size (KB)                                | EEPROM-backup Size (KB) |
|----------------------------------------------------------|-----------------------------------------------------|-------------------------|
| 0000                                                     | DFlash size (512 KB)                                | 0                       |
| 0100                                                     | DFlash size - EEPROM size (512 KB - 64 KB = 448 KB) | 64                      |
| 1111                                                     | DFlash size (512 KB)                                | 0                       |

1. FCCOB5[7:4] = 0000

After clearing CCIF to launch the Program Partition command, the FTFC first verifies that the EEPROM Data Set Size Code and FlexNVM Partition Code in the data flash IFR are erased. If erased, the Program Partition operation command erases the contents of the FlexNVM memory. If the FlexNVM is to be partitioned for emulated EEPROM backup, the allocated emulated EEPROM backup sectors are formatted for emulated EEPROM use. Finally, the partition codes are programmed into the data flash IFR using the values provided. The Program Partition command also verifies that the partition codes read back correctly after programming. The CCIF flag is set after the Program Partition operation operation completes.

Prior to launching the Program Partition command, the data flash IFR must be in an erased state, which can be accomplished by executing the Erase All Blocks or Erase All Blocks Unsecure commands or by an external request (see Triggering an erase all external to the flash module).

**Table 10. Program Partition command error handling**

| Error Condition                                                                                                                           | Error Bit      |
|-------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                                                                                            | FSTAT[ACCERR]  |
| The EEPROM data size and FlexNVM partition code bytes are not initially 0xFFFF                                                            | FSTAT[ACCERR]  |

## Chapter 4

# CMD\_VERIFY\_MAC

The Verify MAC command verifies a MAC of a given MESSAGE, which can be multiple 128-bit blocks of data, against a provided MAC. The MESSAGE to compare, starting with the leftmost bit of the MAC, are given in the MESSAGE\_LENGTH. A MAC\_LENGTH value of 0 is interpreted by SHE to compare all bits of the MAC. The function returns an error if the length provided for message has another length than stated in MESSAGE\_LENGTH. Input DATA1-DATAn until all messages are entered, with the expected MAC being the last entry after all DATA are input, i.e., MAC will be the position of block N+1 for 'N' number of DATA blocks. The provided MAC\_LENGTH must be greater than or equal to the minimum MAC length set by the PGMPART command. Failure to meet this condition will result in an ERC\_GENERAL\_ERROR.

All padding is to be done according to SHE specification using MESSAGE\_LENGTH.

$$n = \text{CEIL}(\text{MESSAGE\_LENGTH} / 128)$$

The first example shows 6 DATA blocks followed by the expected MAC, with the output overwriting the DATA1 block at the end of the operation with the MAC verification status.

The continuation examples show DATA1-10 by continuing from the first example but DATA7 would be written in place of the CMAC from the first example, followed by continuation with DATA8 which follows on the next page. Finally ending in DATA10 for this example, following with the expected CMAC value after the DATA 10 entry.

**Table 11. Verify MAC command details**

| Parameter                                                                                                                                                                                                                                                                                                                            | Direction | Width   |

## Chapter 5

# Program Partition command

The Program Partition command prepares the FlexNVM block for use as data flash, emulated EEPROM backup data memory, or a combination of both and initializes the FlexRAM. The Program Partition command must not be launched from flash memory, since flash memory resources are not accessible during Program Partition command execution. After partitioning for emulated EEPROM activity, the flash module must be reset before any emulated EEPROM activity can be performed.

The Program Partition command is expected to be run on fresh parts before other FTFM and CSEc commands are launched.

### CAUTION

While different partitions of the FlexNVM are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM Partition Code choices affect the endurance and data retention characteristics of the device.

Interrupting a Program Partition operation (due to power loss, reset, supplies out of specified operational ranges, or any other reasons) can leave the partition codes in an indeterminate state. The user must take appropriate counter measures to prevent data loss in case of an interrupted Program Partition operation.

Table 12. Program Partition command FCCOB requirements

| FCCOB Number | FCCOB Contents [7:0]                                                                                                                                                                                                                                         |

| 001                                                 | 1 to 5                                                                          | 128                                                                    |
| 010                                                 | 1 to 10                                                                         | 256                                                                    |
| 011                                                 | 1 to 20                                                                         | 512                                                                    |

1. FCCOB1 [6:3] = 00000

For non-CSEc enabled parts, the number of User Keys must be configured as 2'b00 (no keys).

For non-CSEc enabled parts, the number of Flash Keys must be set to 0 (no keys). The BKRON value in FCCOB6 is ignored and left unprogrammed/erased (1'b1) if the CSEc Key Size is 0.

For CSEc enabled parts, the number of Flash Keys is user configurable and the allocated space will assume that the MASTER\_ECU\_KEY, BOOT\_MAC\_KEY and BOOT\_MAC are there if any keys are enabled. These keys will occupy 3 key slots of the allocated space leaving up to 20 key slots available for user keys (KEY\_<n>).

#### NOTE

For CSEc enabled parts, once Flash Keys are allocated (regardless of being initialized or not), the SHE spec requirement of not erasing Flash Keys without authentication will apply. This will mean Authentication (DBG\_CHAL and DBG\_AUTH) commands must be run and pass (removing all Flash Keys) before erase of the FlexNVM (all Flash Keys are backed up in EFlash). Thus, the Erase All Blocks and Erase All Blocks Unsecure commands will not work, nor will the Erase Flash Block command if the FlexNVM is selected. Additionally if any Flash Keys are write protected, they cannot be erased/removed, thus the FlexNVM cannot be erased and the Authentication process will not pass.

Table 14. Security Flag Extension (SFE)

| Security Flag Extension Code<br>SFE (FCCOB2[7:0]) <sup>1</sup> | Results                                      |
|----------------------------------------------------------------|----------------------------------------------|
| SFE == 0x00                                                    | User Key 'Verify Only' attribute not enabled |
| 0x00                                                           | User Key 'Verify Only' attribute enabled     |

1. FCCOB2[7:1] is ignored

The enhanced Security Flag Extension (SFE) feature is an extension to the SHE specification. For standard SHE usage model, the user should configure this feature as 'not enabled' (SFE set to 0x00). This addition is to provide capability to flag a key as 'VERIFY\_ONLY'. That is, the user can configure SFE set to 0x01 and then use the LOAD\_KEY command to add a new attribute to the key which would tell the GENERATE\_MAC command that the key is to be used only by the VERIFY\_MAC command (by configuring SFE as 'enabled' and then using LOAD\_KEY to set the new VERIFY\_ONLY attribute on that key).

The VERIFY\_ONLY attribute has no effect if the KEY\_USAGE attribute is '0'.

See the CMD\_LOAD\_KEY command for more information on the new attribute.

When FCCOB1[7] equals 0x1, the content of FCCOB7[6:0] sets the minimum MAC length for VERIFY\_MAC commands for both data and pointer methods (FCCOB7[7] is ignored). A value of 0x0 is interpreted as 128-bits, while values 0x1 to 0x7F are directly interpreted as 1 to 127-bits.

When FCCOB1[7] equals 0x0, the value of FCCOB7 is ignored, instead using 1-bit as the minimum MAC length for VERIFY\_MAC commands.

Table 15. Valid emulated EEPROM data set size codes

| EEPROM Data Set Size Code (FCCOB4)<br>EEESIZE (FCCOB4[3:0]) <sup>1</sup> | EEPROM Data Set Size (KB) |
|--------------------------------------------------------------------------|---------------------------|
| 0010                                                                     | 4                         |
| 1111                                                                     | 0 <sup>2</sup>            |

1. FCCOB4[7:4] = 0000

2. EEPROM Data Set Size must be set to 0 Bytes when the FlexNVM Partition Code is set for no EEPROM.

Table 16. Valid FlexNVM partition codes

| FlexNVM Partition Code DEPART<br>(FCCOB5[3:0]) <sup>1</sup> | Data flash Size (KB) | EEPROM-backup Size (KB) |

1. FCCOB5[7:4] = 0000

After clearing CCIF to launch the Program Partition command, the FTFM first verifies that the EEPROM Data Set Size Code and FlexNVM Partition Code in the data flash IFR are erased. If erased, the Program Partition command erases the contents of the FlexNVM memory. If the FlexNVM is to be partitioned for emulated EEPROM backup, the allocated emulated EEPROM backup sectors are formatted for emulated EEPROM use. Finally, the partition codes are programmed into the data flash IFR using the values provided. The Program Partition command also verifies that the partition codes read back correctly after programming. The CCIF flag is set after the Program Partition operation completes.

Prior to launching the Program Partition command, the data flash IFR must be in an erased state, which can be accomplished by executing the Erase All Blocks Unsecure command or by an external request (see Triggering an erase all external to the flash module).

Table 17. Program Partition command error handling

| Error Condition                                                 | Error Bit     |
|-----------------------------------------------------------------|---------------|
| Command not available in current mode/security                  | FSTAT[ACCERR] |
| Invalid Key Size Code is entered (see Table 13 for valid codes) | FSTAT[ACCERR] |
| FCCOB1[6:3] != 00000                                            | FSTAT[ACCERR] |
| FCCOB1[6:0] > 0 for non-CSEc enabled parts                      | FSTAT[ACCERR] |
| FCCOB1[6:0] > 0, when EEPROM-backup size is 0 KB                | FSTAT[ACCERR] |
| FCCOB1[6:0] > 0, when SFE = 0x01                                | FSTAT[ACCERR] |
| FCCOB1[6:0] > 0, when FCCOB3[0] = 1                             | FSTAT[ACCERR] |

| An uncorrectable ECC fault was detected while reading the FlexRAM                                                                         | FSTAT[MGSTAT1] |

## Chapter 6

# CMD\_VERIFY\_MAC

The Verify MAC command verifies a MAC of a given MESSAGE, which can be multiple 128-bit blocks of data, against a provided for MAC. The MESSAGE to compare, starting with the leftmost bit of the MAC, are given in the MESSAGE\_LENGTH. The value 0 is not allowed and is interpreted by SHE to compare all bits of the MAC. The function returns an error if the provided for message has another length than stated in MESSAGE\_LENGTH. Input DATA1-DATAn until all messages are entered, with the expected MAC being the last entry after all DATA are input, i.e., MAC will be the position of block N+1 for 'N' number of DATA blocks. The provided MAC\_LENGTH must be greater than or equal to the minimum MAC length set by the PGMPART command. Failure to meet this condition will result in an ERC\_GENERAL\_ERROR.

All padding is to be done according to SHE specification using MESSAGE\_LENGTH.

$$n = \text{CIEL}(\text{MESSAGE\_LENGTH} / 128)$$

The first example shows 6 DATA blocks followed by the expected MAC, with the output overwriting the DATA1 block at the end of the operation with the MAC verification status.

The continuation examples show DATA1-10 by continuing from the first example but DATA7 would be written in place of the CMAC from the first example, followed by continuation with DATA8 which follows on the next page. Finally ending in DATA10 for this example, following with the expected CMAC value after the DATA 10 entry.

# Legal information

## Definitions

**Draft** — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

## Disclaimers

**Limited warranty and liability** — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

**Right to make changes** — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

**Applications** — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

**Terms and conditions of commercial sale** — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at <http://www.nxp.com/profile/terms>, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

**Export control** — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

**Translations** — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

**Security** — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at [PSIRT@nxp.com](mailto:PSIRT@nxp.com)) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

**Suitability for use in automotive applications (functional safety)** — This NXP product has been qualified for use in automotive applications. It has been developed in accordance with ISO 26262, and has been ASIL classified accordingly. If this product is used by customer in the development of, or for incorporation into, products or services (a) used in safety critical applications or (b) in which failure could lead to death, personal injury, or severe physical or environmental damage (such products and services hereinafter referred to as "Critical Applications"), then customer makes the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, safety, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. As such, customer assumes all risk related to use of any products in Critical Applications and NXP and its suppliers shall not be liable for any such use by customer. Accordingly, customer will indemnify and hold NXP harmless from any claims, liabilities, damages and associated costs and expenses (including attorneys' fees) that NXP may incur related to customer's incorporation of any product in a Critical Application.

**NXP B.V.** — NXP B.V. is not an operating company and it does not distribute or sell products.

| 6.2.7                    | CRC.....                                                               | 111  |
| 6.2.8                    | Diversity of system resources.....                                     | 111  |
| <b>Chapter 7</b>         |                                                                        |      |
| <b>CM4 Overview</b>      |                                                                        |      |
| 7.1                      | Arm Cortex-M4F core configuration.....                                 | 113  |

| Section number | Title                                                                                      | Page |
|----------------|--------------------------------------------------------------------------------------------|------|
| 7.1.1          | Buses, interconnects, and interfaces.....                                                  | 114  |
| 7.1.2          | System Tick Timer.....                                                                     | 114  |
| 7.1.3          | Debug facilities.....                                                                      | 114  |
| 7.1.4          | Caches.....                                                                                | 115  |
| 7.1.5          | Core privilege levels.....                                                                 | 115  |
| 7.2            | Nested Vectored Interrupt Controller (NVIC) Configuration.....                             | 116  |
| 7.2.1          | Interrupt priority levels.....                                                             | 116  |
| 7.2.2          | Non-maskable interrupt.....                                                                | 117  |
| 7.2.3          | Determining the bitfield and register location for configuring a particular interrupt..... | 117  |
| 7.3            | Asynchronous Wake-up Interrupt Controller (AWIC) Configuration.....                        | 118  |
| 7.3.1          | Wake-up sources.....                                                                       | 118  |
| 7.4            | FPU configuration.....                                                                     | 119  |
| 7.5            | JTAG controller configuration.....                                                         | 120  |

## Chapter 8 CM0+ Overview

|       |                                                                                            |     |
|-------|--------------------------------------------------------------------------------------------|-----|
| 8.1   | Arm Cortex-M0+ core introduction.....                                                      | 121 |
| 8.1.1 | Buses, interconnects, and interfaces.....                                                  | 122 |
| 8.1.2 | System tick timer.....                                                                     | 122 |
| 8.1.3 | Debug facilities.....                                                                      | 122 |
| 8.1.4 | Core privilege levels.....                                                                 | 122 |
| 8.2   | Nested vectored interrupt controller (NVIC) .....                                          | 123 |
| 8.2.1 | Interrupt priority levels.....                                                             | 123 |
| 8.2.2 | Non-maskable interrupt.....                                                                | 123 |
| 8.2.3 | Determining the bitfield and register location for configuring a particular interrupt..... | 123 |
| 8.3   | AWIC introduction.....                                                                     | 124 |
| 8.3.1 | Wake-up sources.....                                                                       | 124 |

## Chapter 9 Micro Trace Buffer (MTB)

|     |                   |     |
|-----|-------------------|-----|
| 9.1 | Introduction..... | 127 |
|-----|-------------------|-----|

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 9.1.1          | Overview.....                           | 127  |
| 9.1.2          | Features.....                           | 129  |
| 9.1.3          | Modes of operation.....                 | 130  |
| 9.2            | Memory map and register definition..... | 130  |
| 9.2.1          | MTB_DWT Memory Map.....                 | 131  |

## Chapter 10 Miscellaneous Control Module (MCM)

|         |                                                                |     |
|---------|----------------------------------------------------------------|-----|
| 10.1    | Chip-specific MCM information.....                             | 143 |
| 10.2    | Introduction.....                                              | 144 |
| 10.2.1  | Features.....                                                  | 144 |
| 10.3    | Memory map/register descriptions.....                          | 144 |
| 10.3.1  | Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC).....    | 145 |
| 10.3.2  | Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC).....   | 146 |
| 10.3.3  | Core Platform Control Register (MCM_CPCR).....                 | 147 |
| 10.3.4  | Interrupt Status and Control Register (MCM_ISCR).....          | 150 |
| 10.3.5  | Process ID Register (MCM_PID).....                             | 153 |
| 10.3.6  | Compute Operation Control Register (MCM_CPO).....              | 154 |
| 10.3.7  | Local Memory Descriptor Register (MCM_LMDR <sub>n</sub> )..... | 155 |
| 10.3.8  | Local Memory Descriptor Register2 (MCM_LMDR2).....             | 158 |
| 10.3.9  | LMEM Parity and ECC Control Register (MCM_LMPECR).....         | 162 |
| 10.3.10 | LMEM Parity and ECC Interrupt Register (MCM_LMPEIR).....       | 163 |
| 10.3.11 | LMEM Fault Address Register (MCM_LMFAR).....                   | 164 |
| 10.3.12 | LMEM Fault Attribute Register (MCM_LMFATR).....                | 165 |
| 10.3.13 | LMEM Fault Data High Register (MCM_LMFDHR).....                | 166 |
| 10.3.14 | LMEM Fault Data Low Register (MCM_LMFDLR).....                 | 166 |
| 10.4    | Functional description.....                                    | 167 |
| 10.4.1  | Interrupts.....                                                | 167 |

## Chapter 11 System Integration Module (SIM)

| Section number | Title                                     | Page |
|----------------|-------------------------------------------|------|
| 11.1           | Chip-specific SIM information.....        | 169  |
| 11.1.1         | SIM register/bitfield implementation..... | 169  |
| 11.2           | Introduction.....                         | 178  |
| 11.2.1         | Features.....                             | 178  |
| 11.3           | Memory map and register definition.....   | 178  |
| 11.3.1         | SIM register descriptions.....            | 179  |

## Chapter 12

### Port Control and Interrupts (PORT)

|        |                                                          |     |
|--------|----------------------------------------------------------|-----|
| 12.1   | Chip-specific PORT information.....                      | 205 |
| 12.1.1 | Number of PCRs.....                                      | 205 |
| 12.1.2 | Finding address for PORTx_PCRn .....                     | 206 |
| 12.1.3 | I/O configuration sequence .....                         | 206 |
| 12.1.4 | Digital input filter configuration sequence .....        | 207 |
| 12.1.5 | Reset pin configuration .....                            | 208 |
| 12.2   | Introduction.....                                        | 208 |
| 12.2.1 | Overview.....                                            | 208 |
| 12.2.2 | Features.....                                            | 208 |
| 12.2.3 | Modes of operation.....                                  | 209 |
| 12.3   | External signal description.....                         | 210 |
| 12.4   | Detailed signal description.....                         | 210 |
| 12.5   | Memory map and register definition.....                  | 210 |
| 12.5.1 | Pin Control Register n (PORT_PCRn).....                  | 213 |
| 12.5.2 | Global Pin Control Low Register (PORT_GPCLR).....        | 216 |
| 12.5.3 | Global Pin Control High Register (PORT_GPCHR).....       | 216 |
| 12.5.4 | Global Interrupt Control Low Register (PORT_GICLR).....  | 217 |
| 12.5.5 | Global Interrupt Control High Register (PORT_GICHR)..... | 217 |
| 12.5.6 | Interrupt Status Flag Register (PORT_ISFR).....          | 218 |
| 12.5.7 | Digital Filter Enable Register (PORT_DFER).....          | 219 |
| 12.5.8 | Digital Filter Clock Register (PORT_DFCR).....           | 219 |

| Section number | Title                                          | Page |
|----------------|------------------------------------------------|------|
| 12.5.9         | Digital Filter Width Register (PORT_DFWR)..... | 220  |
| 12.6           | Functional description.....                    | 220  |
| 12.6.1         | Pin control.....                               | 220  |
| 12.6.2         | Global pin control.....                        | 221  |
| 12.6.3         | Global interrupt control.....                  | 222  |
| 12.6.4         | External interrupts.....                       | 222  |
| 12.6.5         | Digital filter.....                            | 223  |

## Chapter 13

### General-Purpose Input/Output (GPIO)

|        |                                         |     |
|--------|-----------------------------------------|-----|
| 13.1   | Chip-specific GPIO information.....     | 225 |
| 13.1.1 | Instantiation information.....          | 225 |
| 13.1.2 | GPIO ports memory map.....              | 225 |
| 13.1.3 | GPIO register reset values .....        | 226 |
| 13.2   | Introduction.....                       | 226 |
| 13.2.1 | Features.....                           | 227 |
| 13.2.2 | Modes of operation.....                 | 227 |
| 13.2.3 | GPIO signal descriptions.....           | 227 |
| 13.3   | Memory map and register definition..... | 228 |
| 13.3.1 | GPIO register descriptions.....         | 228 |
| 13.4   | Functional description.....             | 236 |
| 13.4.1 | General-purpose input.....              | 236 |
| 13.4.2 | General-purpose output.....             | 236 |

## Chapter 14

### Crossbar Switch Lite (AXBS-Lite)

|        |                                          |     |
|--------|------------------------------------------|-----|
| 14.1   | Chip-specific AXBS-Lite information..... | 239 |
| 14.1.1 | Crossbar Switch master assignments.....  | 239 |
| 14.1.2 | Crossbar Switch slave assignments.....   | 239 |
| 14.2   | Introduction.....                        | 240 |
| 14.2.1 | Features.....                            | 240 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 14.3           | Functional Description.....                 | 241  |
| 14.3.1         | General operation.....                      | 241  |
| 14.3.2         | Arbitration.....                            | 241  |
| 14.4           | Initialization/application information..... | 243  |

## Chapter 15

### Memory Protection Unit (MPU)

|         |                                                                        |     |
|---------|------------------------------------------------------------------------|-----|
| 15.1    | Chip-specific MPU information.....                                     | 245 |
| 15.1.1  | MPU Slave Port Assignments.....                                        | 245 |
| 15.1.2  | MPU Logical Bus Master Assignments.....                                | 246 |
| 15.1.3  | Current PID.....                                                       | 246 |
| 15.1.4  | Region descriptors and slave port configuration.....                   | 246 |
| 15.2    | Introduction.....                                                      | 247 |
| 15.3    | Overview.....                                                          | 247 |
| 15.3.1  | Block diagram.....                                                     | 247 |
| 15.3.2  | Features.....                                                          | 248 |
| 15.4    | MPU register descriptions.....                                         | 249 |
| 15.4.1  | MPU memory map.....                                                    | 250 |
| 15.4.2  | Control/Error Status Register (CESR).....                              | 252 |
| 15.4.3  | Error Address Register, slave port n (EAR0 - EAR4).....                | 254 |
| 15.4.4  | Error Detail Register, slave port n (EDR0 - EDR4).....                 | 256 |
| 15.4.5  | Region Descriptor n, Word 0 (RGD0_WORD0 - RGD15_WORD0).....            | 257 |
| 15.4.6  | Region Descriptor 0, Word 1 (RGD0_WORD1).....                          | 258 |
| 15.4.7  | Region Descriptor 0, Word 2 (RGD0_WORD2).....                          | 259 |
| 15.4.8  | Region Descriptor 0, Word 3 (RGD0_WORD3).....                          | 262 |
| 15.4.9  | Region Descriptor n, Word 1 (RGD1_WORD1 - RGD15_WORD1).....            | 264 |
| 15.4.10 | Region Descriptor n, Word 2 (RGD1_WORD2 - RGD15_WORD2).....            | 265 |
| 15.4.11 | Region Descriptor n, Word 3 (RGD1_WORD3 - RGD15_WORD3).....            | 268 |
| 15.4.12 | Region Descriptor Alternate Access Control 0 (RGDAAC0).....            | 269 |
| 15.4.13 | Region Descriptor Alternate Access Control n (RGDAAC1 - RGDAAC15)..... | 272 |

| Section number | Title                                               | Page |
|----------------|-----------------------------------------------------|------|
| 15.5           | Functional description.....                         | 275  |
| 15.5.1         | Access evaluation macro.....                        | 275  |
| 15.5.2         | Putting it all together and error terminations..... | 277  |
| 15.5.3         | Power management.....                               | 277  |
| 15.6           | Initialization information.....                     | 278  |
| 15.7           | Application information.....                        | 278  |

## Chapter 16 Peripheral Bridge (AIPS-Lite)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 16.1   | Chip-specific AIPS information..... | 281 |
| 16.1.1 | Instantiation information.....      | 281 |
| 16.1.2 | Memory maps.....                    | 281 |
| 16.2   | Introduction.....                   | 283 |
| 16.2.1 | Features.....                       | 283 |
| 16.2.2 | General operation.....              | 283 |
| 16.3   | Memory map/register definition..... | 284 |
| 16.3.1 | AIPS register descriptions.....     | 284 |
| 16.4   | Functional description.....         | 328 |
| 16.4.1 | Access support.....                 | 328 |

## Chapter 17 Direct Memory Access Multiplexer (DMAMUX)

|        |                                       |     |
|--------|---------------------------------------|-----|
| 17.1   | Chip-specific DMAMUX information..... | 329 |
| 17.1.1 | Number of channels .....              | 329 |
| 17.1.2 | DMA transfers via TRGMUX trigger..... | 329 |
| 17.2   | Introduction.....                     | 330 |
| 17.2.1 | Overview.....                         | 330 |
| 17.2.2 | Features.....                         | 330 |
| 17.2.3 | Modes of operation.....               | 331 |
| 17.3   | Memory map/register definition.....   | 331 |
| 17.3.1 | DMAMUX register descriptions.....     | 331 |

| Section number | Title                                                 | Page |
|----------------|-------------------------------------------------------|------|
| 17.4           | Functional description.....                           | 333  |
| 17.4.1         | DMA channels with periodic triggering capability..... | 333  |
| 17.4.2         | DMA channels with no triggering capability.....       | 336  |
| 17.4.3         | Always-enabled DMA sources.....                       | 336  |
| 17.5           | Initialization/application information.....           | 337  |
| 17.5.1         | Reset.....                                            | 337  |
| 17.5.2         | Enabling and configuring sources.....                 | 337  |

## Chapter 18

### Enhanced Direct Memory Access (eDMA)

|        |                                             |     |
|--------|---------------------------------------------|-----|
| 18.1   | Chip-specific eDMA information .....        | 341 |
| 18.1.1 | Seamless eDMA transfer .....                | 341 |
| 18.1.2 | Number of channels .....                    | 342 |
| 18.2   | Overview.....                               | 342 |
| 18.2.1 | Block diagram.....                          | 342 |
| 18.2.2 | Block parts.....                            | 343 |
| 18.2.3 | Features.....                               | 344 |
| 18.3   | Memory map/register definition.....         | 346 |
| 18.3.1 | TCD memory.....                             | 346 |
| 18.3.2 | TCD initialization.....                     | 346 |
| 18.3.3 | TCD structure.....                          | 346 |
| 18.3.4 | Reserved memory and fields.....             | 347 |
| 18.3.5 | DMA register descriptions.....              | 347 |
| 18.4   | Functional description.....                 | 396 |
| 18.4.1 | Modes of operation.....                     | 396 |
| 18.4.2 | eDMA basic data flow.....                   | 397 |
| 18.4.3 | Fault reporting and handling.....           | 400 |
| 18.4.4 | Channel preemption.....                     | 402 |
| 18.5   | Initialization/application information..... | 403 |
| 18.5.1 | eDMA initialization.....                    | 403 |

| Section number | Title                                                                   | Page |
|----------------|-------------------------------------------------------------------------|------|
| 18.5.2         | Programming errors.....                                                 | 405  |
| 18.5.3         | Arbitration mode considerations.....                                    | 406  |
| 18.5.4         | DMA transfer examples.....                                              | 406  |
| 18.5.5         | Monitoring transfer descriptor status.....                              | 410  |
| 18.5.6         | Channel linking.....                                                    | 411  |
| 18.5.7         | Dynamic programming.....                                                | 413  |
| 18.5.8         | Suspend/resume a DMA channel with active hardware service requests..... | 416  |

## Chapter 19 Trigger MUX Control (TRGMUX)

|        |                                         |     |
|--------|-----------------------------------------|-----|
| 19.1   | Chip-specific TRGMUX information.....   | 419 |
| 19.1.1 | Module interconnectivity.....           | 419 |
| 19.1.2 | TRGMUX register information.....        | 423 |
| 19.2   | Introduction.....                       | 423 |
| 19.3   | Features.....                           | 423 |
| 19.4   | Memory map and register definition..... | 424 |
| 19.4.1 | TRGMUX register descriptions.....       | 424 |

## Chapter 20 External Watchdog Monitor (EWM)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 20.1   | Chip-specific EWM information ..... | 463 |
| 20.1.1 | EWM_OUT signal configuration.....   | 463 |
| 20.1.2 | EWM Memory Map access.....          | 463 |
| 20.1.3 | EWM low-power modes.....            | 463 |
| 20.2   | Introduction.....                   | 463 |
| 20.2.1 | Features.....                       | 464 |
| 20.2.2 | Modes of Operation.....             | 464 |
| 20.2.3 | Block Diagram.....                  | 465 |
| 20.3   | EWM Signal Descriptions.....        | 466 |
| 20.4   | Memory Map/Register Definition..... | 467 |
| 20.4.1 | EWM register descriptions.....      | 467 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 20.5           | Functional Description.....                 | 472  |
| 20.5.1         | The EWM_OUT_b Signal.....                   | 472  |
| 20.5.2         | EWM_OUT_b pin state in low power modes..... | 473  |
| 20.5.3         | The EWM_in Signal.....                      | 473  |
| 20.5.4         | EWM Counter.....                            | 474  |
| 20.5.5         | EWM Compare Registers.....                  | 474  |
| 20.5.6         | EWM Refresh Mechanism.....                  | 474  |
| 20.5.7         | EWM Interrupt.....                          | 475  |
| 20.5.8         | Counter clock prescaler.....                | 475  |

## Chapter 21 Error Injection Module (EIM)

|        |                                                                                |     |
|--------|--------------------------------------------------------------------------------|-----|
| 21.1   | Chip-specific EIM information.....                                             | 477 |
| 21.1.1 | EIM channel assignments.....                                                   | 477 |
| 21.2   | Introduction.....                                                              | 477 |
| 21.2.1 | Overview.....                                                                  | 477 |
| 21.2.2 | Features.....                                                                  | 479 |
| 21.3   | EIM register descriptions.....                                                 | 479 |
| 21.3.1 | EIM memory map.....                                                            | 480 |
| 21.3.2 | Error Injection Module Configuration Register (EIMCR).....                     | 480 |
| 21.3.3 | Error Injection Channel Enable register (EICHEN).....                          | 481 |
| 21.3.4 | Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD1_WORD0)..... | 484 |
| 21.3.5 | Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)..... | 486 |
| 21.4   | Functional description.....                                                    | 487 |
| 21.4.1 | Error injection scenarios.....                                                 | 487 |

## Chapter 22 Error Reporting Module (ERM)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 22.1   | Chip-specific ERM information.....  | 489 |
| 22.1.1 | Sources of memory error events..... | 489 |
| 22.2   | Introduction.....                   | 489 |

| Section number | Title                                                  | Page |
|----------------|--------------------------------------------------------|------|
| 22.2.1         | Overview.....                                          | 489  |
| 22.2.2         | Features.....                                          | 490  |
| 22.3           | ERM register descriptions.....                         | 490  |
| 22.3.1         | ERM memory map.....                                    | 490  |
| 22.3.2         | ERM Configuration Register 0 (CR0).....                | 491  |
| 22.3.3         | ERM Status Register 0 (SR0).....                       | 493  |
| 22.3.4         | ERM Memory n Error Address Register (EAR0 - EAR1)..... | 495  |
| 22.4           | Functional description.....                            | 496  |
| 22.4.1         | Single-bit correction events.....                      | 496  |
| 22.4.2         | Non-correctable error events.....                      | 497  |
| 22.5           | Initialization.....                                    | 498  |

## Chapter 23 Watchdog timer (WDOG)

|        |                                         |     |
|--------|-----------------------------------------|-----|
| 23.1   | Chip-specific WDOG information.....     | 499 |
| 23.1.1 | WDOG clocks.....                        | 499 |
| 23.1.2 | WDOG low-power modes.....               | 499 |
| 23.1.3 | Default watchdog timeout .....          | 500 |
| 23.1.4 | Watchdog Timeout Reaction.....          | 500 |
| 23.2   | Introduction.....                       | 501 |
| 23.2.1 | Features.....                           | 501 |
| 23.2.2 | Block diagram.....                      | 502 |
| 23.3   | Memory map and register definition..... | 502 |
| 23.3.1 | WDOG register descriptions.....         | 502 |
| 23.4   | Functional description.....             | 509 |
| 23.4.1 | Clock source.....                       | 509 |
| 23.4.2 | Watchdog refresh mechanism.....         | 510 |
| 23.4.3 | Configuring the Watchdog.....           | 511 |
| 23.4.4 | Using interrupts to delay resets.....   | 512 |
| 23.4.5 | Backup reset.....                       | 513 |

| Section number | Title                                           | Page |
|----------------|-------------------------------------------------|------|
| 23.4.6         | Functionality in debug and low-power modes..... | 513  |
| 23.4.7         | Fast testing of the watchdog.....               | 514  |
| 23.5           | Application Information.....                    | 515  |
| 23.5.1         | Disable Watchdog.....                           | 515  |
| 23.5.2         | Disable Watchdog after Reset.....               | 516  |
| 23.5.3         | Configure Watchdog.....                         | 516  |
| 23.5.4         | Refreshing the Watchdog.....                    | 517  |

## Chapter 24 Cyclic Redundancy Check (CRC)

|        |                                           |     |
|--------|-------------------------------------------|-----|
| 24.1   | Chip-specific CRC information.....        | 519 |
| 24.2   | Introduction.....                         | 519 |
| 24.2.1 | Features.....                             | 519 |
| 24.2.2 | Block diagram.....                        | 520 |
| 24.2.3 | Modes of operation.....                   | 520 |
| 24.3   | Memory map and register descriptions..... | 520 |
| 24.3.1 | CRC register descriptions.....            | 521 |
| 24.4   | Functional description.....               | 525 |
| 24.4.1 | CRC initialization/reinitialization.....  | 525 |
| 24.4.2 | CRC calculations.....                     | 525 |
| 24.4.3 | Transpose feature.....                    | 526 |
| 24.4.4 | CRC result complement.....                | 528 |
| 24.5   | Use cases.....                            | 529 |
| 24.5.1 | CRC Control Register programming.....     | 529 |
| 24.5.2 | Expected read data fields.....            | 530 |

## Chapter 25 Reset and Boot

|        |                           |     |
|--------|---------------------------|-----|
| 25.1   | Introduction.....         | 533 |
| 25.2   | Reset.....                | 533 |
| 25.2.1 | Power-on reset (POR)..... | 534 |

| Section number | Title                     | Page |
|----------------|---------------------------|------|
| 25.2.2         | System reset sources..... | 534  |
| 25.2.3         | MCU Resets.....           | 538  |
| 25.2.4         | Reset pin .....           | 538  |
| 25.2.5         | Debug resets.....         | 539  |
| 25.3           | Boot.....                 | 540  |
| 25.3.1         | Boot sources.....         | 540  |
| 25.3.2         | FOPT boot options.....    | 540  |
| 25.3.3         | Boot sequence.....        | 541  |

## Chapter 26 Reset Control Module (RCM)

|        |                                                        |     |
|--------|--------------------------------------------------------|-----|
| 26.1   | Chip-specific RCM information.....                     | 543 |
| 26.1.1 | RCM register information .....                         | 543 |
| 26.2   | Reset pin filter operation in STOP1/2 modes .....      | 544 |
| 26.3   | Introduction.....                                      | 544 |
| 26.4   | Reset memory map and register descriptions.....        | 544 |
| 26.4.1 | Version ID Register (RCM_VERID).....                   | 545 |
| 26.4.2 | Parameter Register (RCM_PARAM).....                    | 546 |
| 26.4.3 | System Reset Status Register (RCM_SRS).....            | 548 |
| 26.4.4 | Reset Pin Control register (RCM_RPC).....              | 551 |
| 26.4.5 | Sticky System Reset Status Register (RCM_SSRS).....    | 553 |
| 26.4.6 | System Reset Interrupt Enable Register (RCM_SRIE)..... | 555 |

## Chapter 27 Clock Distribution

|        |                                       |     |
|--------|---------------------------------------|-----|
| 27.1   | Introduction.....                     | 559 |
| 27.2   | High level clocking diagram.....      | 559 |
| 27.3   | Clock definitions.....                | 560 |
| 27.4   | Internal clocking requirements.....   | 562 |
| 27.4.1 | Clock divider values after reset..... | 567 |
| 27.4.2 | HSRUN mode clocking.....              | 567 |

| Section number | Title                     | Page |
|----------------|---------------------------|------|
| 27.4.3         | VLPR mode clocking.....   | 567  |
| 27.4.4         | VLPR/VLPS mode entry..... | 568  |
| 27.5           | Clock Gating.....         | 568  |
| 27.6           | Module clocks.....        | 568  |

## Chapter 28

### System Clock Generator (SCG)

|         |                                                             |     |
|---------|-------------------------------------------------------------|-----|
| 28.1    | Chip-specific SCG information.....                          | 583 |
| 28.1.1  | Register reset values.....                                  | 583 |
| 28.1.2  | Supported frequency ranges.....                             | 583 |
| 28.1.3  | Oscillator and SPLL guidelines.....                         | 584 |
| 28.1.4  | System clock switching .....                                | 584 |
| 28.1.5  | System clock and clock monitor requirement .....            | 585 |
| 28.2    | Introduction.....                                           | 585 |
| 28.2.1  | Features.....                                               | 586 |
| 28.3    | Memory Map/Register Definition.....                         | 587 |
| 28.3.1  | Version ID Register (SCG_VERID).....                        | 588 |
| 28.3.2  | Parameter Register (SCG_PARAM).....                         | 588 |
| 28.3.3  | Clock Status Register (SCG_CSR).....                        | 589 |
| 28.3.4  | Run Clock Control Register (SCG_RCCR).....                  | 592 |
| 28.3.5  | VLPR Clock Control Register (SCG_VCCR).....                 | 594 |
| 28.3.6  | HSRUN Clock Control Register (SCG_HCCR).....                | 596 |
| 28.3.7  | SCG CLKOUT Configuration Register (SCG_CLKOUTCNFG).....     | 598 |
| 28.3.8  | System OSC Control Status Register (SCG_SOSCCSR).....       | 600 |
| 28.3.9  | System OSC Divide Register (SCG_SOSCDIV).....               | 602 |
| 28.3.10 | System Oscillator Configuration Register (SCG_SOSCCFG)..... | 603 |
| 28.3.11 | Slow IRC Control Status Register (SCG_SIRCCSR).....         | 604 |
| 28.3.12 | Slow IRC Divide Register (SCG_SIRCDIV).....                 | 605 |
| 28.3.13 | Slow IRC Configuration Register (SCG_SIRCCFG).....          | 606 |
| 28.3.14 | Fast IRC Control Status Register (SCG_FIRCCSR).....         | 607 |

| Section number | Title                                                 | Page |
|----------------|-------------------------------------------------------|------|
| 28.3.15        | Fast IRC Divide Register (SCG_FIRCDIV).....           | 609  |
| 28.3.16        | Fast IRC Configuration Register (SCG_FIRCCFG).....    | 610  |
| 28.3.17        | System PLL Control Status Register (SCG_SPLLCSR)..... | 611  |
| 28.3.18        | System PLL Divide Register (SCG_SPLLDIV).....         | 613  |
| 28.3.19        | System PLL Configuration Register (SCG_SPLLCFG).....  | 613  |
| 28.4           | Functional description.....                           | 615  |
| 28.4.1         | SCG Clock Mode Transitions.....                       | 615  |

## Chapter 29

### Peripheral Clock Controller (PCC)

|         |                                           |     |
|---------|-------------------------------------------|-----|
| 29.1    | Chip-specific PCC information.....        | 619 |
| 29.1.1  | PCC register information.....             | 619 |
| 29.2    | Introduction.....                         | 624 |
| 29.3    | Features.....                             | 624 |
| 29.4    | Functional description.....               | 625 |
| 29.5    | Memory map and register definition.....   | 625 |
| 29.6    | PCC register descriptions.....            | 625 |
| 29.6.1  | PCC memory map.....                       | 625 |
| 29.6.2  | PCC FTFC Register (PCC_FTFC).....         | 627 |
| 29.6.3  | PCC DMAMUX Register (PCC_DMAMUX).....     | 628 |
| 29.6.4  | PCC FlexCAN0 Register (PCC_FlexCAN0)..... | 630 |
| 29.6.5  | PCC FlexCAN1 Register (PCC_FlexCAN1)..... | 631 |
| 29.6.6  | PCC FTM3 Register (PCC_FTM3).....         | 633 |
| 29.6.7  | PCC ADC1 Register (PCC_ADC1).....         | 634 |
| 29.6.8  | PCC FlexCAN2 Register (PCC_FlexCAN2)..... | 636 |
| 29.6.9  | PCC LPSPI0 Register (PCC_LPSPI0).....     | 637 |
| 29.6.10 | PCC LPSPI1 Register (PCC_LPSPI1).....     | 639 |
| 29.6.11 | PCC LPSPI2 Register (PCC_LPSPI2).....     | 640 |
| 29.6.12 | PCC PDB1 Register (PCC_PDB1).....         | 642 |
| 29.6.13 | PCC CRC Register (PCC_CRC).....           | 644 |

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 29.6.14        | PCC PDB0 Register (PCC_PDB0).....       | 645  |
| 29.6.15        | PCC LPIT Register (PCC_LPIT).....       | 647  |
| 29.6.16        | PCC FTM0 Register (PCC_FTM0).....       | 648  |
| 29.6.17        | PCC FTM1 Register (PCC_FTM1).....       | 650  |
| 29.6.18        | PCC FTM2 Register (PCC_FTM2).....       | 651  |
| 29.6.19        | PCC ADC0 Register (PCC_ADC0).....       | 653  |
| 29.6.20        | PCC RTC Register (PCC_RTC).....         | 655  |
| 29.6.21        | PCC LPTMR0 Register (PCC_LPTMR0).....   | 656  |
| 29.6.22        | PCC PORTA Register (PCC_PORTA).....     | 658  |
| 29.6.23        | PCC PORTB Register (PCC_PORTB).....     | 660  |
| 29.6.24        | PCC PORTC Register (PCC_PORTC).....     | 661  |
| 29.6.25        | PCC PORTD Register (PCC_PORTD).....     | 663  |
| 29.6.26        | PCC PORTE Register (PCC_PORTE).....     | 664  |
| 29.6.27        | PCC SAI0 Register (PCC_SAI0).....       | 666  |
| 29.6.28        | PCC SAI1 Register (PCC_SAI1).....       | 667  |
| 29.6.29        | PCC FlexIO Register (PCC_FlexIO).....   | 669  |
| 29.6.30        | PCC EWM Register (PCC_EWM).....         | 670  |
| 29.6.31        | PCC LPI2C0 Register (PCC_LPI2C0).....   | 672  |
| 29.6.32        | PCC LPI2C1 Register (PCC_LPI2C1).....   | 673  |
| 29.6.33        | PCC LPUART0 Register (PCC_LPUART0)..... | 675  |
| 29.6.34        | PCC LPUART1 Register (PCC_LPUART1)..... | 676  |
| 29.6.35        | PCC LPUART2 Register (PCC_LPUART2)..... | 678  |
| 29.6.36        | PCC FTM4 Register (PCC_FTM4).....       | 680  |
| 29.6.37        | PCC FTM5 Register (PCC_FTM5).....       | 681  |
| 29.6.38        | PCC FTM6 Register (PCC_FTM6).....       | 683  |
| 29.6.39        | PCC FTM7 Register (PCC_FTM7).....       | 685  |
| 29.6.40        | PCC CMP0 Register (PCC_CMP0).....       | 686  |
| 29.6.41        | PCC QSPI Register (PCC_QSPI).....       | 688  |
| 29.6.42        | PCC ENET Register (PCC_ENET).....       | 690  |

| Section number                        | Title                                                 | Page |
|---------------------------------------|-------------------------------------------------------|------|
| <b>Chapter 30</b>                     |                                                       |      |
| <b>Clock Monitoring Unit (CMU)</b>    |                                                       |      |
| 30.1                                  | CMU chip-specific information.....                    | 693  |
| 30.2                                  | Introduction.....                                     | 694  |
| 30.2.1                                | Basic operation.....                                  | 695  |
| 30.2.2                                | Features.....                                         | 696  |
| 30.3                                  | CMU_FC register descriptions.....                     | 696  |
| 30.3.1                                | CMU_FC Memory map.....                                | 696  |
| 30.3.2                                | Global Configuration Register (GCR).....              | 697  |
| 30.3.3                                | Reference Count Configuration Register (RCCR).....    | 698  |
| 30.3.4                                | High Threshold Configuration Register (HTCR).....     | 699  |
| 30.3.5                                | Low Threshold Configuration Register (LTCR).....      | 700  |
| 30.3.6                                | Status Register (SR).....                             | 701  |
| 30.3.7                                | Interrupt Enable Register (IER).....                  | 702  |
| 30.4                                  | Functional description.....                           | 705  |
| 30.4.1                                | Monitored clock lost.....                             | 705  |
| 30.5                                  | Programming guidelines.....                           | 705  |
| 30.5.1                                | Programming HFREF and LFREF.....                      | 705  |
| 30.5.2                                | Programming RCCR[REF_CNT].....                        | 706  |
| 30.5.3                                | CMU_FC programming sequence.....                      | 707  |
| <b>Chapter 31</b>                     |                                                       |      |

| 31.1                                  | Introduction.....                                     | 709  |
| 31.2                                  | Flash Memory Controller and flash memory modules..... | 709  |
| 31.3                                  | SRAM configuration.....                               | 710  |
| 31.3.1                                | SRAM sizes.....                                       | 710  |
| 31.3.2                                | SRAM accessibility.....                               | 711  |
| 31.3.3                                | SRAM arbitration and priority control.....            | 712  |
| 31.3.4                                | SRAM retention: power modes and resets.....           | 712  |

| Section number | Title | Page |
|----------------|-------|------|
|----------------|-------|------|

|        |                                                                                          |     |
|--------|------------------------------------------------------------------------------------------|-----|
| 31.3.5 | SRAM access: Behavior of device when in accessing a memory with multi-bit ECC error..... | 713 |
|--------|------------------------------------------------------------------------------------------|-----|

## Chapter 32 PRAM Controller (PRAMC)

|        |                                               |     |
|--------|-----------------------------------------------|-----|
| 32.1   | PRAMC chip-specific information .....         | 715 |
| 32.2   | Introduction.....                             | 715 |
| 32.3   | Memory map and register definition.....       | 716 |
| 32.4   | Functional description.....                   | 716 |
| 32.4.1 | Error Correcting Code (ECC).....              | 716 |
| 32.4.2 | Read/Write introduction.....                  | 717 |
| 32.4.3 | Reads.....                                    | 717 |
| 32.4.4 | Writes.....                                   | 718 |
| 32.4.5 | Late write hits.....                          | 719 |
| 32.5   | Initialization / application information..... | 720 |

## Chapter 33 Local Memory Controller (LMEM)

|        |                                      |     |
|--------|--------------------------------------|-----|
| 33.1   | Chip-specific LMEM information ..... | 721 |
| 33.1.1 | LMEM region description.....         | 721 |
| 33.1.2 | LMEM SRAM sizes.....                 | 721 |
| 33.2   | Introduction.....                    | 721 |
| 33.2.1 | Block Diagram.....                   | 722 |
| 33.2.2 | Cache features.....                  | 723 |
| 33.3   | Memory Map/Register Definition.....  | 725 |
| 33.3.1 | LMEM register descriptions.....      | 725 |
| 33.4   | Functional Description.....          | 734 |
| 33.4.1 | LMEM Function.....                   | 734 |
| 33.4.2 | SRAM Function.....                   | 735 |
| 33.4.3 | Cache Function.....                  | 737 |
| 33.4.4 | Cache Control.....                   | 738 |

## Chapter 34 Miscellaneous System Control Module (MSCM)

| Section number | Title                                           | Page |
|----------------|-------------------------------------------------|------|
| 34.1           | Chip-specific MSCM information.....             | 743  |
| 34.1.1         | Chip-specific TMLSZ/TMUSZ information.....      | 743  |
| 34.1.2         | Chip-specific register information.....         | 743  |
| 34.2           | Overview.....                                   | 744  |
| 34.3           | Chip Configuration and Boot.....                | 744  |
| 34.4           | MSCM Memory Map/Register Definition.....        | 745  |
| 34.4.1         | CPU Configuration Memory Map and Registers..... | 745  |
| 34.4.2         | MSCM register descriptions.....                 | 745  |

## Chapter 35 Flash Memory Controller (FMC)

|        |                                                 |     |
|--------|-------------------------------------------------|-----|
| 35.1   | Chip-specific FMC information.....              | 777 |
| 35.1.1 | FMC masters.....                                | 777 |
| 35.1.2 | Program flash and Data flash port width.....    | 778 |
| 35.1.3 | ECC Implementation for NVM .....                | 778 |
| 35.2   | Introduction.....                               | 778 |
| 35.2.1 | Overview.....                                   | 778 |
| 35.2.2 | Features.....                                   | 779 |
| 35.3   | Modes of operation.....                         | 780 |
| 35.4   | External signal description.....                | 780 |
| 35.5   | Functional description.....                     | 780 |
| 35.5.1 | Default configuration.....                      | 780 |
| 35.5.2 | Speculative reads.....                          | 780 |
| 35.6   | Initialization and application information..... | 781 |

## Chapter 36 Flash Memory Module (FTFC)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 36.1   | Chip-specific FTFC information..... | 783 |
| 36.1.1 | Flash memory types.....             | 784 |
| 36.1.2 | Flash memory sizes.....             | 784 |
| 36.1.3 | Flash memory map.....               | 803 |

| Section number | Title                                                    | Page |
|----------------|----------------------------------------------------------|------|
| 36.1.4         | Flash memory security.....                               | 804  |
| 36.1.5         | Power mode restrictions on flash memory programming..... | 804  |
| 36.1.6         | Flash memory modes.....                                  | 804  |
| 36.1.7         | Erase all contents of flash memory.....                  | 804  |
| 36.1.8         | Customize MCU operations via FTFC_FOPT register.....     | 805  |
| 36.1.9         | Simultaneous operations on PFLASH read partitions .....  | 805  |
| 36.2           | Introduction.....                                        | 805  |
| 36.2.1         | Features.....                                            | 806  |
| 36.2.2         | Block diagram.....                                       | 808  |
| 36.2.3         | Glossary.....                                            | 809  |
| 36.3           | External signal description.....                         | 811  |
| 36.4           | Memory map and registers.....                            | 812  |
| 36.4.1         | Flash configuration field description.....               | 812  |
| 36.4.2         | Program flash 0 IFR map.....                             | 812  |
| 36.4.3         | Data flash 0 IFR map.....                                | 813  |
| 36.4.4         | Register descriptions.....                               | 814  |
| 36.5           | Functional description.....                              | 832  |
| 36.5.1         | Flash protection.....                                    | 832  |
| 36.5.2         | FlexNVM description.....                                 | 834  |
| 36.5.3         | Interrupts.....                                          | 837  |
| 36.5.4         | Flash operation in low-power modes.....                  | 838  |
| 36.5.5         | Functional modes of operation.....                       | 838  |
| 36.5.6         | Flash memory reads and ignored writes.....               | 838  |
| 36.5.7         | Read while write (RWW).....                              | 839  |
| 36.5.8         | Flash program and erase.....                             | 839  |
| 36.5.9         | FTFC command operations.....                             | 839  |
| 36.5.10        | Margin read commands.....                                | 846  |
| 36.5.11        | Flash command descriptions.....                          | 847  |
| 36.5.12        | Security.....                                            | 873  |

| Section number | Title                                     | Page |
|----------------|-------------------------------------------|------|
| 36.5.13        | Cryptographic Services Engine (CSEc)..... | 875  |
| 36.5.14        | Reset sequence.....                       | 913  |

## Chapter 37 Flash Memory Module (FTFM)

|         |                                            |      |
|---------|--------------------------------------------|------|
| 37.1    | Chip-specific FTFM information .....       | 915  |
| 37.2    | Introduction.....                          | 915  |
| 37.2.1  | Features.....                              | 916  |
| 37.2.2  | Block diagram.....                         | 918  |
| 37.2.3  | Glossary.....                              | 918  |
| 37.3    | External signal description.....           | 920  |
| 37.4    | Memory map and registers.....              | 921  |
| 37.4.1  | Flash configuration field description..... | 921  |
| 37.4.2  | Program flash 0 IFR map.....               | 922  |
| 37.4.3  | Data flash 0 IFR map.....                  | 922  |
| 37.4.4  | Register descriptions.....                 | 923  |
| 37.5    | Functional description.....                | 944  |
| 37.5.1  | Flash protection.....                      | 944  |
| 37.5.2  | FlexMemory description.....                | 946  |
| 37.5.3  | Interrupts.....                            | 950  |
| 37.5.4  | Flash operation in low-power modes.....    | 950  |
| 37.5.5  | Flash memory reads and ignored writes..... | 951  |
| 37.5.6  | Read while write (RWW).....                | 951  |
| 37.5.7  | Flash program and erase.....               | 952  |
| 37.5.8  | Flash command operations.....              | 952  |
| 37.5.9  | Flash command descriptions.....            | 960  |
| 37.5.10 | Security.....                              | 985  |
| 37.5.11 | Cryptographic Services Engine (CSEc).....  | 987  |
| 37.5.12 | Reset sequence.....                        | 1026 |

## Chapter 38

| Section number | Title                                                                   | Page |
|----------------|-------------------------------------------------------------------------|------|
|                | <b>Quad Serial Peripheral Interface (QuadSPI)</b>                       |      |
| 38.1           | Chip-specific QuadSPI information.....                                  | 1029 |
| 38.1.1         | Overview.....                                                           | 1029 |
| 38.1.2         | Memory size requirement .....                                           | 1029 |
| 38.1.3         | QuadSPI register reset values.....                                      | 1030 |
| 38.1.4         | Use case.....                                                           | 1030 |
| 38.1.5         | Supported read modes.....                                               | 1030 |
| 38.1.6         | External memory options.....                                            | 1031 |
| 38.1.7         | Recommended software configuration.....                                 | 1031 |
| 38.1.8         | Recommended programming sequence.....                                   | 1032 |
| 38.1.9         | Clock ratio between QuadSPI clocks .....                                | 1032 |
| 38.1.10        | QuadSPI_MCR[SCLKCFG] implementation .....                               | 1032 |
| 38.1.11        | QuadSPI_SOCCR[SOC CFG] implementation .....                             | 1033 |
| 38.2           | Introduction.....                                                       | 1035 |
| 38.2.1         | Features.....                                                           | 1035 |
| 38.2.2         | Block Diagram.....                                                      | 1036 |
| 38.2.3         | QuadSPI Modes of Operation.....                                         | 1037 |
| 38.2.4         | Acronyms and Abbreviations.....                                         | 1038 |
| 38.2.5         | Glossary for QuadSPI module.....                                        | 1038 |
| 38.3           | External Signal Description.....                                        | 1040 |
| 38.3.1         | Driving External Signals.....                                           | 1041 |
| 38.4           | Memory Map and Register Definition.....                                 | 1043 |
| 38.4.1         | Register Write Access.....                                              | 1043 |
| 38.4.2         | Peripheral Bus Register Descriptions.....                               | 1044 |
| 38.4.3         | Serial Flash Address Assignment.....                                    | 1088 |
| 38.5           | Flash memory mapped AMBA bus.....                                       | 1089 |
| 38.5.1         | AHB Bus Access Considerations.....                                      | 1090 |
| 38.5.2         | Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A..... | 1090 |
| 38.5.3         | Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B..... | 1091 |

| Section number | Title                                                      | Page |
|----------------|------------------------------------------------------------|------|
| 38.5.4         | AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31).....        | 1092 |
| 38.6           | Interrupt Signals.....                                     | 1095 |
| 38.7           | Functional Description.....                                | 1095 |
| 38.7.1         | Serial Flash Access Schemes.....                           | 1095 |
| 38.7.2         | Normal Mode.....                                           | 1096 |
| 38.7.3         | HyperRAM Support.....                                      | 1115 |
| 38.8           | Initialization/Application Information.....                | 1116 |
| 38.8.1         | Power Up and Reset.....                                    | 1116 |
| 38.8.2         | Available Status/Flag Information.....                     | 1116 |
| 38.8.3         | Flash Device Selection.....                                | 1119 |
| 38.8.4         | DMA Usage.....                                             | 1119 |
| 38.9           | Byte Ordering - Endianness.....                            | 1123 |
| 38.9.1         | Programming Flash Data.....                                | 1124 |
| 38.9.2         | Reading Flash Data into the RX Buffer.....                 | 1124 |
| 38.9.3         | Reading Flash Data into the AHB Buffer.....                | 1125 |
| 38.10          | Driving Flash Control Signals in Single and Dual Mode..... | 1126 |
| 38.11          | Serial Flash Devices.....                                  | 1126 |
| 38.11.1        | Example Sequences.....                                     | 1126 |
| 38.12          | Sampling of Serial Flash Input Data.....                   | 1132 |
| 38.12.1        | Basic Description.....                                     | 1132 |
| 38.12.2        | Supported read modes.....                                  | 1133 |
| 38.12.3        | Data Strobe (DQS) sampling method.....                     | 1136 |
| 38.13          | Data Input Hold Requirement of Flash.....                  | 1139 |

## Chapter 39 Power Management

|      |                                       |      |
|------|---------------------------------------|------|
| 39.1 | Introduction.....                     | 1141 |
| 39.2 | Power modes description.....          | 1141 |
| 39.3 | Entering and exiting power modes..... | 1143 |
| 39.4 | Clocking modes.....                   | 1143 |

| Section number | Title                                                    | Page |
|----------------|----------------------------------------------------------|------|
| 39.4.1         | Clock gating.....                                        | 1143 |
| 39.4.2         | Stop mode options.....                                   | 1143 |
| 39.4.3         | DMA wake-up.....                                         | 1144 |
| 39.4.4         | Compute Operation (CPO).....                             | 1145 |
| 39.4.5         | Peripheral Doze.....                                     | 1146 |
| 39.5           | Power mode transitions.....                              | 1147 |
| 39.6           | Shutdown sequencing for power modes.....                 | 1148 |
| 39.7           | Power mode restrictions on flash memory programming..... | 1148 |
| 39.8           | Module operation in available power modes.....           | 1149 |
| 39.9           | QuadSPI, Ethernet, and SAI operation .....               | 1152 |

## Chapter 40 System Mode Controller (SMC)

|        |                                                  |      |
|--------|--------------------------------------------------|------|
| 40.1   | Introduction.....                                | 1153 |
| 40.2   | Modes of operation.....                          | 1153 |
| 40.3   | Memory map and register descriptions.....        | 1155 |
| 40.3.1 | SMC Version ID Register (SMC_VERID).....         | 1156 |
| 40.3.2 | SMC Parameter Register (SMC_PARAM).....          | 1157 |
| 40.3.3 | Power Mode Protection register (SMC_PMPROT)..... | 1158 |
| 40.3.4 | Power Mode Control register (SMC_PMCTRL).....    | 1159 |
| 40.3.5 | Stop Control Register (SMC_STOPCTRL).....        | 1161 |
| 40.3.6 | Power Mode Status register (SMC_PMSTAT).....     | 1163 |
| 40.4   | Functional description.....                      | 1163 |
| 40.4.1 | Power mode transitions.....                      | 1164 |
| 40.4.2 | Power mode entry/exit sequencing.....            | 1165 |
| 40.4.3 | Run modes.....                                   | 1168 |
| 40.4.4 | Stop modes.....                                  | 1170 |
| 40.4.5 | Debug in low power modes.....                    | 1171 |

## Chapter 41 Power Management Controller (PMC)

| Section number | Title                                              | Page |
|----------------|----------------------------------------------------|------|
| 41.1           | Chip-specific PMC information .....                | 1173 |
| 41.2           | Modes supported.....                               | 1173 |
| 41.2.1         | LVD, LVW and LVR threshold levels.....             | 1173 |
| 41.3           | Introduction.....                                  | 1173 |
| 41.4           | Features.....                                      | 1173 |
| 41.5           | Modes of Operation.....                            | 1174 |
| 41.5.1         | Full Performance Mode (FPM).....                   | 1174 |
| 41.5.2         | Low Power Mode (LPM).....                          | 1174 |
| 41.6           | Low Voltage Detect (LVD) System.....               | 1174 |
| 41.6.1         | Low Voltage Reset (LVR) Operation.....             | 1175 |
| 41.6.2         | LVD Interrupt Operation.....                       | 1175 |
| 41.6.3         | Low-voltage warning (LVW) interrupt operation..... | 1175 |
| 41.7           | Memory Map and Register Definition.....            | 1176 |
| 41.7.1         | PMC register descriptions.....                     | 1176 |

## Chapter 42 Power Management Controller (PMC)

|        |                                                    |      |
|--------|----------------------------------------------------|------|
| 42.1   | Chip-specific PMC information .....                | 1183 |
| 42.2   | Introduction.....                                  | 1183 |
| 42.3   | Features.....                                      | 1183 |
| 42.4   | Modes of Operation.....                            | 1183 |
| 42.4.1 | Full Performance Mode (FPM).....                   | 1183 |
| 42.4.2 | Low Power Mode (LPM).....                          | 1184 |
| 42.5   | Low Voltage Reset and Detect System.....           | 1184 |
| 42.5.1 | Low Voltage Reset (LVR) Operation.....             | 1184 |
| 42.5.2 | Low-voltage warning (LVW) interrupt operation..... | 1184 |
| 42.6   | Memory Map and Register Definition.....            | 1185 |
| 42.6.1 | PMC register descriptions.....                     | 1185 |

## Chapter 43 ADC Configuration

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 43.1           | Instantiation information.....          | 1193 |
| 43.1.1         | Number of ADC channels.....             | 1193 |
| 43.1.2         | ADC Connections/Channel Assignment..... | 1194 |
| 43.2           | Register implementation.....            | 1195 |
| 43.3           | DMA Support on ADC.....                 | 1195 |
| 43.4           | ADC Hardware Interleaved Channels.....  | 1196 |
| 43.5           | ADC internal supply monitoring.....     | 1197 |
| 43.6           | ADC Reference Options.....              | 1197 |
| 43.7           | ADC Trigger Sources.....                | 1198 |
| 43.7.1         | PDB triggering scheme.....              | 1200 |
| 43.7.2         | TRGMUX trigger scheme.....              | 1201 |
| 43.8           | Trigger Selection.....                  | 1202 |
| 43.9           | Trigger Latching and Arbitration.....   | 1203 |
| 43.10          | ADC triggering configurations .....     | 1205 |
| 43.11          | ADC low-power modes.....                | 1212 |
| 43.12          | ADC Trigger Concept – Use Case.....     | 1212 |
| 43.13          | ADC calibration scheme.....             | 1214 |
| 43.14          | S32K11X to S32K14X difference .....     | 1215 |

## Chapter 44

### Analog-to-Digital Converter (ADC)

|        |                                    |      |
|--------|------------------------------------|------|
| 44.1   | Chip-specific ADC information..... | 1217 |
| 44.2   | Introduction.....                  | 1217 |
| 44.2.1 | Features.....                      | 1217 |
| 44.2.2 | Block diagram.....                 | 1218 |
| 44.3   | ADC signal descriptions.....       | 1219 |
| 44.3.1 | Analog Power (VDDA).....           | 1219 |
| 44.3.2 | Analog Ground (VSSA).....          | 1219 |
| 44.3.3 | Voltage Reference Select.....      | 1219 |
| 44.3.4 | Analog Channel Inputs (ADx).....   | 1220 |

| Section number | Title                                                                     | Page |
|----------------|---------------------------------------------------------------------------|------|
| 44.4           | ADC register descriptions.....                                            | 1220 |
| 44.4.1         | ADC Memory map.....                                                       | 1220 |
| 44.4.2         | ADC Status and Control Register 1 (SC1A - aSC1P).....                     | 1222 |
| 44.4.3         | ADC Configuration Register 1 (CFG1).....                                  | 1225 |
| 44.4.4         | ADC Configuration Register 2 (CFG2).....                                  | 1227 |
| 44.4.5         | ADC Data Result Registers (RA - aRP).....                                 | 1228 |
| 44.4.6         | Compare Value Registers (CV1 - CV2).....                                  | 1230 |
| 44.4.7         | Status and Control Register 2 (SC2).....                                  | 1231 |
| 44.4.8         | Status and Control Register 3 (SC3).....                                  | 1234 |
| 44.4.9         | BASE Offset Register (BASE_OFS).....                                      | 1235 |
| 44.4.10        | ADC Offset Correction Register (OFS).....                                 | 1236 |
| 44.4.11        | USER Offset Correction Register (USR_OFS).....                            | 1237 |
| 44.4.12        | ADC X Offset Correction Register (XOFS).....                              | 1238 |
| 44.4.13        | ADC Y Offset Correction Register (YOFS).....                              | 1239 |
| 44.4.14        | ADC Gain Register (G).....                                                | 1240 |
| 44.4.15        | ADC User Gain Register (UG).....                                          | 1242 |
| 44.4.16        | ADC General Calibration Value Register S (CLPS).....                      | 1243 |
| 44.4.17        | ADC Plus-Side General Calibration Value Register 3 (CLP3).....            | 1244 |
| 44.4.18        | ADC Plus-Side General Calibration Value Register 2 (CLP2).....            | 1245 |
| 44.4.19        | ADC Plus-Side General Calibration Value Register 1 (CLP1).....            | 1245 |
| 44.4.20        | ADC Plus-Side General Calibration Value Register 0 (CLP0).....            | 1246 |
| 44.4.21        | ADC Plus-Side General Calibration Value Register X (CLPX).....            | 1247 |
| 44.4.22        | ADC Plus-Side General Calibration Value Register 9 (CLP9).....            | 1248 |
| 44.4.23        | ADC General Calibration Offset Value Register S (CLPS_OFS).....           | 1249 |
| 44.4.24        | ADC Plus-Side General Calibration Offset Value Register 3 (CLP3_OFS)..... | 1250 |

| 44.5.7         | User-defined offset function.....                                         | 1269 |
| 44.5.8         | MCU Normal Stop mode operation.....                                       | 1270 |

## Chapter 45 Comparator (CMP)

|        |                                     |      |
|--------|-------------------------------------|------|
| 45.1   | Chip-specific CMP information.....  | 1271 |
| 45.1.1 | Instantiation information.....      | 1271 |
| 45.1.2 | CMP input connections.....          | 1271 |
| 45.1.3 | CMP external references.....        | 1273 |
| 45.1.4 | External window/sample input.....   | 1273 |
| 45.1.5 | CMP trigger mode.....               | 1273 |
| 45.1.6 | Programming recommendation.....     | 1274 |
| 45.1.7 | S32K11X to S32K14X difference ..... | 1275 |
| 45.2   | Introduction.....                   | 1275 |
| 45.3   | Features.....                       | 1275 |
| 45.3.1 | CMP features.....                   | 1275 |
| 45.3.2 | 8-bit DAC key features.....         | 1276 |
| 45.3.3 | ANMUX key features.....             | 1277 |
| 45.4   | CMP, DAC, and ANMUX diagram.....    | 1277 |
| 45.5   | CMP block diagram.....              | 1278 |

| Section number | Title                                          | Page |
|----------------|------------------------------------------------|------|
| 45.6           | CMP pin descriptions.....                      | 1280 |
| 45.6.1         | External pins.....                             | 1280 |
| 45.7           | CMP functional modes.....                      | 1281 |
| 45.7.1         | Disabled mode (# 1).....                       | 1282 |
| 45.7.2         | Continuous mode (#s 2A & 2B).....              | 1283 |
| 45.7.3         | Sampled, Non-Filtered mode (#s 3A & 3B).....   | 1283 |
| 45.7.4         | Sampled, Filtered mode (#s 4A & 4B).....       | 1285 |
| 45.7.5         | Windowed mode (#s 5A & 5B).....                | 1287 |
| 45.7.6         | Windowed/Resampled mode (# 6).....             | 1289 |
| 45.7.7         | Windowed/Filtered mode (#7).....               | 1290 |
| 45.8           | Memory map/register definitions.....           | 1291 |
| 45.8.1         | CMP Control Register 0 (CMP_C0).....           | 1291 |
| 45.8.2         | CMP Control Register 1 (CMP_C1).....           | 1295 |
| 45.8.3         | CMP Control Register 2 (CMP_C2).....           | 1298 |
| 45.9           | CMP functional description.....                | 1300 |
| 45.9.1         | Initialization.....                            | 1300 |
| 45.9.2         | Low-pass filter.....                           | 1301 |
| 45.10          | Interrupts.....                                | 1303 |
| 45.11          | DMA support.....                               | 1303 |
| 45.12          | DAC functional description.....                | 1304 |
| 45.12.1        | Digital-to-analog converter block diagram..... | 1304 |
| 45.12.2        | DAC resets.....                                | 1304 |
| 45.12.3        | DAC clocks.....                                | 1305 |
| 45.12.4        | DAC interrupts.....                            | 1305 |
| 45.13          | Trigger mode.....                              | 1305 |

## Chapter 46

### Programmable delay block (PDB)

|        |                                    |      |
|--------|------------------------------------|------|
| 46.1   | Chip-specific PDB information..... | 1309 |
| 46.1.1 | Instantiation Information.....     | 1309 |

| Section number | Title                                                 | Page |
|----------------|-------------------------------------------------------|------|
| 46.1.2         | PDB trigger interconnections with ADC and TRGMUX..... | 1310 |
| 46.1.3         | Back-to-back acknowledgement connections.....         | 1310 |
| 46.1.4         | Pulse-Out Enable Register Implementation.....         | 1320 |
| 46.1.5         | S32K11X to S32K14X difference .....                   | 1320 |
| 46.2           | Introduction.....                                     | 1320 |
| 46.2.1         | Features.....                                         | 1320 |
| 46.2.2         | Implementation.....                                   | 1321 |
| 46.2.3         | Back-to-back acknowledgment connections.....          | 1322 |
| 46.2.4         | Block diagram.....                                    | 1322 |
| 46.2.5         | Modes of operation.....                               | 1323 |
| 46.3           | Memory map and register definition.....               | 1324 |
| 46.3.1         | Status and Control register (PDB_SC).....             | 1326 |
| 46.3.2         | Modulus register (PDB_MOD).....                       | 1329 |
| 46.3.3         | Counter register (PDB_CNT).....                       | 1330 |
| 46.3.4         | Interrupt Delay register (PDB_IDLY).....              | 1330 |
| 46.3.5         | Channel n Control register 1 (PDB_CHnC1).....         | 1331 |
| 46.3.6         | Channel n Status register (PDB_CHnS).....             | 1332 |
| 46.3.7         | Channel n Delay 0 register (PDB_CHnDLY0).....         | 1332 |
| 46.3.8         | Channel n Delay 1 register (PDB_CHnDLY1).....         | 1333 |
| 46.3.9         | Channel n Delay 2 register (PDB_CHnDLY2).....         | 1334 |
| 46.3.10        | Channel n Delay 3 register (PDB_CHnDLY3).....         | 1334 |
| 46.3.11        | Channel n Delay 4 register (PDB_CHnDLY4).....         | 1335 |
| 46.3.12        | Channel n Delay 5 register (PDB_CHnDLY5).....         | 1336 |
| 46.3.13        | Channel n Delay 6 register (PDB_CHnDLY6).....         | 1336 |
| 46.3.14        | Channel n Delay 7 register (PDB_CHnDLY7).....         | 1337 |
| 46.3.15        | Pulse-Out n Enable register (PDB_POEN).....           | 1337 |
| 46.3.16        | Pulse-Out n Delay register (PDB_POnDLY).....          | 1338 |
| 46.4           | Functional description.....                           | 1338 |
| 46.4.1         | PDB pre-trigger and trigger outputs.....              | 1338 |

| Section number | Title                                                                             | Page |
|----------------|-----------------------------------------------------------------------------------|------|
| 46.4.2         | PDB trigger input source selection.....                                           | 1341 |
| 46.4.3         | Pulse-Out's.....                                                                  | 1341 |
| 46.4.4         | Updating the delay registers.....                                                 | 1342 |
| 46.4.5         | Interrupts.....                                                                   | 1344 |
| 46.4.6         | DMA.....                                                                          | 1344 |
| 46.5           | Application information.....                                                      | 1344 |
| 46.5.1         | Impact of using the prescaler and multiplication factor on timing resolution..... | 1344 |

## Chapter 47

### FlexTimer Module (FTM)

|         |                                                |      |
|---------|------------------------------------------------|------|
| 47.1    | Chip-specific FTM information.....             | 1347 |
| 47.1.1  | Instantiation Information.....                 | 1347 |
| 47.1.2  | FTM Interrupts.....                            | 1348 |
| 47.1.3  | FTM Fault Detection Inputs.....                | 1349 |
| 47.1.4  | FTM Hardware Triggers and Synchronization..... | 1350 |
| 47.1.5  | FTM Input Capture Options.....                 | 1352 |
| 47.1.6  | FTM Hall sensor support.....                   | 1353 |
| 47.1.7  | FTM Modulation Implementation.....             | 1353 |
| 47.1.8  | FTM Global Time Base.....                      | 1354 |
| 47.1.9  | FTM BDM and debug halt mode.....               | 1355 |
| 47.1.10 | FTM fixed frequency clock .....                | 1355 |
| 47.1.11 | S32K11X to S32K14X difference .....            | 1355 |
| 47.2    | Introduction.....                              | 1357 |
| 47.2.1  | Features.....                                  | 1357 |
| 47.2.2  | Modes of operation.....                        | 1359 |
| 47.2.3  | Block Diagram.....                             | 1359 |
| 47.3    | FTM signal descriptions.....                   | 1361 |
| 47.4    | Memory map and register definition.....        | 1361 |
| 47.4.1  | Memory map.....                                | 1361 |
| 47.4.2  | Register descriptions.....                     | 1362 |

| Section number | Title                                     | Page |
|----------------|-------------------------------------------|------|
| 47.4.3         | FTM register descriptions.....            | 1362 |
| 47.5           | Functional Description.....               | 1419 |
| 47.5.1         | Clock source.....                         | 1419 |
| 47.5.2         | Prescaler.....                            | 1419 |
| 47.5.3         | Counter.....                              | 1420 |
| 47.5.4         | Channel Modes.....                        | 1426 |
| 47.5.5         | Input Capture Mode.....                   | 1428 |
| 47.5.6         | Output Compare mode.....                  | 1433 |
| 47.5.7         | Edge-Aligned PWM (EPWM) mode.....         | 1434 |
| 47.5.8         | Center-Aligned PWM (CPWM) mode.....       | 1436 |
| 47.5.9         | Combine mode.....                         | 1438 |
| 47.5.10        | Modified Combine PWM Mode.....            | 1446 |
| 47.5.11        | Complementary Mode.....                   | 1449 |
| 47.5.12        | Registers updated from write buffers..... | 1451 |
| 47.5.13        | PWM synchronization.....                  | 1452 |
| 47.5.14        | Inverting.....                            | 1468 |
| 47.5.15        | Software Output Control Mode.....         | 1469 |
| 47.5.16        | Deadtime insertion.....                   | 1471 |
| 47.5.17        | Output mask.....                          | 1475 |
| 47.5.18        | Fault Control.....                        | 1476 |
| 47.5.19        | Polarity Control.....                     | 1480 |
| 47.5.20        | Initialization.....                       | 1481 |
| 47.5.21        | Features Priority.....                    | 1481 |
| 47.5.22        | External Trigger.....                     | 1482 |
| 47.5.23        | Initialization Trigger.....               | 1483 |
| 47.5.24        | Capture Test Mode.....                    | 1485 |
| 47.5.25        | DMA.....                                  | 1486 |
| 47.5.26        | Dual Edge Capture Mode.....               | 1487 |
| 47.5.27        | Quadrature Decoder Mode.....              | 1495 |

| Section number | Title                                    | Page |
|----------------|------------------------------------------|------|
| 47.5.28        | Debug mode.....                          | 1501 |
| 47.5.29        | Reload Points.....                       | 1502 |
| 47.5.30        | Global Load.....                         | 1505 |
| 47.5.31        | Global time base (GTB).....              | 1506 |
| 47.5.32        | Channel trigger output.....              | 1507 |
| 47.5.33        | External Control of Channels Output..... | 1508 |
| 47.5.34        | Dithering.....                           | 1508 |
| 47.6           | Reset Overview.....                      | 1519 |
| 47.7           | FTM Interrupts.....                      | 1521 |
| 47.7.1         | Timer Overflow Interrupt.....            | 1521 |
| 47.7.2         | Reload Point Interrupt.....              | 1521 |
| 47.7.3         | Channel (n) Interrupt.....               | 1521 |
| 47.7.4         | Fault Interrupt.....                     | 1521 |
| 47.8           | Initialization Procedure.....            | 1522 |

## Chapter 48

### Low Power Interrupt Timer (LPIT)

|        |                                             |      |
|--------|---------------------------------------------|------|
| 48.1   | Chip-specific LPIT information.....         | 1525 |
| 48.1.1 | Instantiation Information.....              | 1525 |
| 48.1.2 | LPIT/DMA Periodic Trigger Assignments ..... | 1525 |
| 48.1.3 | LPIT input triggers .....                   | 1526 |
| 48.1.4 | LPIT/ADC Trigger.....                       | 1526 |
| 48.1.5 | Current timer value.....                    | 1527 |
| 48.1.6 | S32K11X to S32K14X difference .....         | 1528 |
| 48.2   | Introduction.....                           | 1528 |
| 48.2.1 | Overview.....                               | 1528 |
| 48.2.2 | Block Diagram.....                          | 1529 |
| 48.3   | Modes of operation.....                     | 1530 |
| 48.4   | Memory Map and Registers.....               | 1531 |
| 48.4.1 | LPIT register descriptions.....             | 1531 |

| Section number | Title                           | Page |
|----------------|---------------------------------|------|
| 48.5           | Functional description.....     | 1547 |
| 48.5.1         | LPIT programming model.....     | 1547 |
| 48.5.2         | Initialization.....             | 1548 |
| 48.5.3         | Timer Modes.....                | 1549 |
| 48.5.4         | Trigger Control for Timers..... | 1550 |
| 48.5.5         | Channel Chaining.....           | 1551 |
| 48.5.6         | Detailed timing.....            | 1551 |

## Chapter 49 Low Power Timer (LPTMR)

|        |                                         |      |
|--------|-----------------------------------------|------|
| 49.1   | Chip-specific LPTMR information.....    | 1565 |
| 49.1.1 | Instantiation Information.....          | 1565 |
| 49.1.2 | LPTMR pulse counter input options.....  | 1566 |
| 49.1.3 | S32K11X to S32K14X difference .....     | 1566 |
| 49.2   | Introduction.....                       | 1566 |
| 49.2.1 | Features.....                           | 1566 |
| 49.2.2 | Modes of operation.....                 | 1567 |
| 49.3   | LPTMR signal descriptions.....          | 1567 |
| 49.3.1 | Detailed signal descriptions.....       | 1567 |
| 49.4   | Memory map and register definition..... | 1568 |
| 49.4.1 | LPTMR register descriptions.....        | 1568 |
| 49.5   | Functional description.....             | 1573 |
| 49.5.1 | LPTMR power and reset.....              | 1573 |
| 49.5.2 | LPTMR clocking.....                     | 1574 |
| 49.5.3 | LPTMR prescaler/glitch filter.....      | 1574 |
| 49.5.4 | LPTMR counter.....                      | 1575 |
| 49.5.5 | LPTMR compare.....                      | 1576 |
| 49.5.6 | LPTMR interrupt.....                    | 1576 |
| 49.5.7 | LPTMR hardware trigger.....             | 1577 |

## Chapter 50

| Section number | Title                               | Page |
|----------------|-------------------------------------|------|
|                | <b>Real Time Clock (RTC)</b>        |      |
| 50.1           | Chip-specific RTC information.....  | 1579 |
| 50.1.1         | RTC instantiation.....              | 1579 |
| 50.1.2         | RTC interrupts .....                | 1579 |
| 50.1.3         | Software recommendation.....        | 1579 |
| 50.1.4         | Multiple trigger .....              | 1580 |
| 50.1.5         | S32K11X to S32K14X difference ..... | 1580 |
| 50.2           | Introduction.....                   | 1580 |
| 50.2.1         | Features.....                       | 1580 |
| 50.2.2         | Modes of operation.....             | 1580 |
| 50.2.3         | RTC signal descriptions.....        | 1581 |
| 50.3           | Register definition.....            | 1581 |
| 50.3.1         | RTC register descriptions.....      | 1581 |
| 50.4           | Functional description.....         | 1592 |
| 50.4.1         | Power, clocking, and reset.....     | 1592 |
| 50.4.2         | Time counter.....                   | 1593 |
| 50.4.3         | Compensation.....                   | 1593 |
| 50.4.4         | Time alarm.....                     | 1594 |
| 50.4.5         | Update mode.....                    | 1595 |
| 50.4.6         | Register lock.....                  | 1595 |
| 50.4.7         | Interrupt.....                      | 1595 |

## Chapter 51

### Low Power Serial Peripheral Interface (LPSPI)

|        |                                      |      |
|--------|--------------------------------------|------|
| 51.1   | Chip-specific LPSPI information..... | 1597 |
| 51.1.1 | Instantiation Information.....       | 1597 |
| 51.2   | Introduction.....                    | 1598 |
| 51.2.1 | Features.....                        | 1598 |
| 51.2.2 | Block Diagram.....                   | 1599 |
| 51.2.3 | Modes of operation.....              | 1600 |

| Section number | Title                            | Page |
|----------------|----------------------------------|------|
| 51.2.4         | Signal Descriptions.....         | 1600 |
| 51.3           | Memory Map and Registers.....    | 1601 |
| 51.3.1         | LPSPi register descriptions..... | 1601 |
| 51.4           | Functional description.....      | 1626 |
| 51.4.1         | Clocking and resets.....         | 1626 |
| 51.4.2         | Master Mode.....                 | 1626 |
| 51.4.3         | Slave Mode.....                  | 1632 |
| 51.4.4         | Interrupts and DMA Requests..... | 1634 |
| 51.4.5         | Peripheral Triggers.....         | 1635 |

## Chapter 52

### Low Power Inter-Integrated Circuit (LPI2C)

|        |                                      |      |
|--------|--------------------------------------|------|
| 52.1   | Chip-specific LPI2C information..... | 1637 |
| 52.1.1 | Instantiation information.....       | 1637 |
| 52.2   | Introduction.....                    | 1638 |
| 52.2.1 | Features.....                        | 1638 |
| 52.2.2 | Block Diagram.....                   | 1639 |
| 52.2.3 | Modes of operation.....              | 1640 |
| 52.2.4 | Signal Descriptions.....             | 1640 |
| 52.3   | Functional description.....          | 1641 |
| 52.3.1 | Clocking and Resets.....             | 1641 |
| 52.3.2 | Master Mode.....                     | 1642 |
| 52.3.3 | Slave Mode.....                      | 1648 |
| 52.3.4 | Interrupts and DMA Requests.....     | 1650 |
| 52.3.5 | Peripheral Triggers.....             | 1652 |
| 52.4   | Memory Map and Registers.....        | 1653 |
| 52.4.1 | LPI2C register descriptions.....     | 1653 |

## Chapter 53

### Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

|      |                                       |      |
|------|---------------------------------------|------|
| 53.1 | Chip-specific LPUART information..... | 1693 |
|------|---------------------------------------|------|

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 53.1.1         | Instantiation Information.....          | 1693 |
| 53.2           | Introduction.....                       | 1694 |
| 53.2.1         | Features.....                           | 1694 |
| 53.2.2         | Modes of operation.....                 | 1695 |
| 53.2.3         | Signal Descriptions.....                | 1695 |
| 53.2.4         | Block diagram.....                      | 1695 |
| 53.3           | Register definition.....                | 1697 |
| 53.3.1         | LPUART register descriptions.....       | 1697 |
| 53.4           | Functional description.....             | 1723 |
| 53.4.1         | Clocking and Resets.....                | 1723 |
| 53.4.2         | Baud rate generation.....               | 1723 |
| 53.4.3         | Transmitter functional description..... | 1724 |
| 53.4.4         | Receiver functional description.....    | 1727 |
| 53.4.5         | Additional LPUART functions.....        | 1735 |
| 53.4.6         | Infrared interface.....                 | 1737 |
| 53.4.7         | Interrupts and status flags.....        | 1738 |
| 53.4.8         | Peripheral Triggers.....                | 1739 |

## Chapter 54 Flexible I/O (FlexIO)

|        |                                       |      |
|--------|---------------------------------------|------|
| 54.1   | Chip-specific FlexIO information..... | 1741 |
| 54.1.1 | FlexIO Configuration.....             | 1741 |
| 54.2   | Introduction.....                     | 1741 |
| 54.2.1 | Overview.....                         | 1741 |
| 54.2.2 | Features.....                         | 1742 |
| 54.2.3 | Block Diagram.....                    | 1742 |
| 54.2.4 | Modes of operation.....               | 1743 |
| 54.2.5 | FlexIO Signal Descriptions.....       | 1743 |
| 54.3   | Memory Map and Registers.....         | 1744 |
| 54.3.1 | FLEXIO register descriptions.....     | 1744 |

| Section number    | Title                                                               | Page |
|-------------------|---------------------------------------------------------------------|------|
| 54.4              | Functional description.....                                         | 1768 |
| 54.4.1            | Clocking and Resets.....                                            | 1768 |
| 54.4.2            | Shifter operation.....                                              | 1769 |
| 54.4.3            | Timer Operation.....                                                | 1771 |
| 54.4.4            | Pin operation.....                                                  | 1775 |
| 54.4.5            | Interrupts and DMA Requests.....                                    | 1776 |
| 54.4.6            | Peripheral Triggers.....                                            | 1776 |
| 54.5              | Application Information.....                                        | 1777 |
| 54.5.1            | UART Transmit.....                                                  | 1777 |
| 54.5.2            | UART Receive.....                                                   | 1778 |
| 54.5.3            | SPI Master.....                                                     | 1780 |
| 54.5.4            | SPI Slave.....                                                      | 1782 |
| 54.5.5            | I2C Master.....                                                     | 1783 |
| 54.5.6            | I2S Master.....                                                     | 1785 |
| 54.5.7            | I2S Slave.....                                                      | 1787 |
| <b>Chapter 55</b> |                                                                     |      |
| <b>FlexCAN</b>    |                                                                     |      |
| 55.1              | Chip-specific FlexCAN information.....                              | 1789 |
| 55.1.1            | Instantiation information.....                                      | 1789 |
| 55.1.2            | FlexCAN register information.....                                   | 1790 |
| 55.1.3            | Reset value of MDIS bit.....                                        | 1797 |
| 55.1.4            | FlexCAN external time tick .....                                    | 1797 |
| 55.1.5            | FlexCAN Interrupts.....                                             | 1797 |
| 55.1.6            | FlexCAN Operation in Low Power Modes.....                           | 1798 |
| 55.1.7            | FlexCAN oscillator clock.....                                       | 1798 |
| 55.1.8            | Supported baud rate .....                                           | 1798 |
| 55.1.9            | Requirements for entering FlexCAN modes: Freeze, Disable, Stop..... | 1798 |
| 55.2              | Overview.....                                                       | 1800 |
| 55.2.1            | Block diagram.....                                                  | 1801 |

| Section number | Title                                                | Page |
|----------------|------------------------------------------------------|------|
| 55.2.2         | Features.....                                        | 1801 |
| 55.3           | Functional description.....                          | 1803 |
| 55.3.1         | Modes of operation.....                              | 1804 |
| 55.3.2         | Transmit process.....                                | 1809 |
| 55.3.3         | Arbitration process.....                             | 1811 |
| 55.3.4         | Receive process.....                                 | 1814 |
| 55.3.5         | Matching process.....                                | 1816 |
| 55.3.6         | Receive process under Pretended Networking mode..... | 1821 |
| 55.3.7         | Move process.....                                    | 1825 |
| 55.3.8         | Data coherence.....                                  | 1827 |
| 55.3.9         | Rx FIFO.....                                         | 1830 |
| 55.3.10        | CAN protocol related features.....                   | 1833 |
| 55.3.11        | Clocks.....                                          | 1853 |
| 55.3.12        | Reset.....                                           | 1858 |
| 55.3.13        | Interrupts.....                                      | 1858 |
| 55.3.14        | Bus interface.....                                   | 1859 |
| 55.4           | FlexCAN signal descriptions.....                     | 1862 |
| 55.4.1         | CAN Rx .....                                         | 1863 |
| 55.4.2         | CAN Tx .....                                         | 1863 |
| 55.5           | Memory map/register definition.....                  | 1863 |
| 55.5.1         | FlexCAN memory mapping.....                          | 1863 |
| 55.5.2         | CAN register descriptions.....                       | 1865 |
| 55.5.3         | Message buffer structure.....                        | 1933 |
| 55.5.4         | FlexCAN memory partition for CAN FD.....             | 1940 |
| 55.5.5         | FlexCAN message buffer memory map.....               | 1941 |
| 55.5.6         | Rx FIFO structure.....                               | 1943 |
| 55.6           | Initialization/application information.....          | 1945 |
| 55.6.1         | FlexCAN initialization sequence.....                 | 1945 |

## Chapter 56

| Section number                           | Title                                         | Page |
|------------------------------------------|-----------------------------------------------|------|
| <b>Synchronous Audio Interface (SAI)</b> |                                               |      |
| 56.1                                     | Chip-specific SAI information .....           | 1947 |
| 56.1.1                                   | SAI configuration.....                        | 1947 |
| 56.1.2                                   | Chip-specific register information.....       | 1948 |
| 56.2                                     | Introduction.....                             | 1949 |
| 56.2.1                                   | Features.....                                 | 1949 |
| 56.2.2                                   | Block diagram.....                            | 1949 |
| 56.2.3                                   | Modes of operation.....                       | 1950 |
| 56.3                                     | External signals.....                         | 1951 |
| 56.4                                     | Memory map and register definition.....       | 1951 |
| 56.4.1                                   | I2S register descriptions.....                | 1951 |
| 56.5                                     | Functional description.....                   | 1984 |
| 56.5.1                                   | SAI clocking.....                             | 1984 |
| 56.5.2                                   | SAI resets.....                               | 1986 |
| 56.5.3                                   | Synchronous modes.....                        | 1987 |
| 56.5.4                                   | Frame sync configuration.....                 | 1988 |
| 56.5.5                                   | Data FIFO.....                                | 1988 |
| 56.5.6                                   | Word mask register.....                       | 1992 |
| 56.5.7                                   | Interrupts and DMA requests.....              | 1993 |
| <b>Chapter 57</b>                        |                                               |      |
| <b>Ethernet MAC (ENET)</b>               |                                               |      |
| 57.1                                     | Chip-specific ENET information.....           | 1997 |
| 57.1.1                                   | Software guideline during ENET operation..... | 1997 |
| 57.2                                     | Introduction.....                             | 1997 |
| 57.3                                     | Overview.....                                 | 1998 |
| 57.3.1                                   | Features.....                                 | 1998 |
| 57.3.2                                   | Block diagram.....                            | 2001 |
| 57.4                                     | External signal description.....              | 2001 |
| 57.5                                     | Memory map/register definition.....           | 2003 |

| Section number | Title                                                           | Page |
|----------------|-----------------------------------------------------------------|------|
| 57.5.1         | Interrupt Event Register (ENET_EIR).....                        | 2008 |
| 57.5.2         | Interrupt Mask Register (ENET_EIMR).....                        | 2011 |
| 57.5.3         | Receive Descriptor Active Register (ENET_RDAR).....             | 2014 |
| 57.5.4         | Transmit Descriptor Active Register (ENET_TDAR).....            | 2015 |
| 57.5.5         | Ethernet Control Register (ENET_ECR).....                       | 2016 |
| 57.5.6         | MII Management Frame Register (ENET_MMFR).....                  | 2018 |
| 57.5.7         | MII Speed Control Register (ENET_MSCR).....                     | 2018 |
| 57.5.8         | MIB Control Register (ENET_MIBC).....                           | 2021 |
| 57.5.9         | Receive Control Register (ENET_RCR).....                        | 2022 |
| 57.5.10        | Transmit Control Register (ENET_TCR).....                       | 2025 |
| 57.5.11        | Physical Address Lower Register (ENET_PALR).....                | 2027 |
| 57.5.12        | Physical Address Upper Register (ENET_PAUR).....                | 2027 |
| 57.5.13        | Opcode/Pause Duration Register (ENET_OPD).....                  | 2028 |
| 57.5.14        | Descriptor Individual Upper Address Register (ENET_IAUR).....   | 2028 |
| 57.5.15        | Descriptor Individual Lower Address Register (ENET_IALR).....   | 2029 |
| 57.5.16        | Descriptor Group Upper Address Register (ENET_GAUR).....        | 2029 |
| 57.5.17        | Descriptor Group Lower Address Register (ENET_GALR).....        | 2030 |
| 57.5.18        | Transmit FIFO Watermark Register (ENET_TFWR).....               | 2030 |
| 57.5.19        | Receive Descriptor Ring Start Register (ENET_RDSR).....         | 2031 |
| 57.5.20        | Transmit Buffer Descriptor Ring Start Register (ENET_TDSR)..... | 2032 |
| 57.5.21        | Maximum Receive Buffer Size Register (ENET_MRBR).....           | 2033 |
| 57.5.22        | Receive FIFO Section Full Threshold (ENET_RSFL).....            | 2034 |
| 57.5.23        | Receive FIFO Section Empty Threshold (ENET_RSEM).....           | 2034 |
| 57.5.24        | Receive FIFO Almost Empty Threshold (ENET_RAEM).....            | 2035 |
| 57.5.25        | Receive FIFO Almost Full Threshold (ENET_RAFL).....             | 2035 |
| 57.5.26        | Transmit FIFO Section Empty Threshold (ENET_TSEM).....          | 2036 |
| 57.5.27        | Transmit FIFO Almost Empty Threshold (ENET_TAEM).....           | 2036 |
| 57.5.28        | Transmit FIFO Almost Full Threshold (ENET_TAFL).....            | 2037 |
| 57.5.29        | Transmit Inter-Packet Gap (ENET_TIPG).....                      | 2037 |

| Section number | Title                                                                                      | Page |
|----------------|--------------------------------------------------------------------------------------------|------|
| 57.5.30        | Frame Truncation Length (ENET_FTRL).....                                                   | 2038 |
| 57.5.31        | Transmit Accelerator Function Configuration (ENET_TACC).....                               | 2038 |
| 57.5.32        | Receive Accelerator Function Configuration (ENET_RACC).....                                | 2039 |
| 57.5.33        | Reserved Statistic Register (ENET_RMON_T_DROP).....                                        | 2040 |
| 57.5.34        | Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS).....                              | 2041 |
| 57.5.35        | Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT).....                          | 2041 |
| 57.5.36        | Tx Multicast Packets Statistic Register (ENET_RMON_T_MC_PKT).....                          | 2042 |
| 57.5.37        | Tx Packets with CRC/Align Error Statistic Register (ENET_RMON_T_CRC_ALIGN).....            | 2042 |
| 57.5.38        | Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET_RMON_T_UNDERSIZE).....    | 2042 |
| 57.5.39        | Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET_RMON_T_OVERSIZE).....     | 2043 |
| 57.5.40        | Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_T_FRAG).....       | 2043 |
| 57.5.41        | Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET_RMON_T_JAB)..... | 2044 |
| 57.5.42        | Tx Collision Count Statistic Register (ENET_RMON_T_COL).....                               | 2044 |
| 57.5.43        | Tx 64-Byte Packets Statistic Register (ENET_RMON_T_P64).....                               | 2044 |
| 57.5.44        | Tx 65- to 127-byte Packets Statistic Register (ENET_RMON_T_P65TO127).....                  | 2045 |
| 57.5.45        | Tx 128- to 255-byte Packets Statistic Register (ENET_RMON_T_P128TO255).....                | 2045 |
| 57.5.46        | Tx 256- to 511-byte Packets Statistic Register (ENET_RMON_T_P256TO511).....                | 2046 |
| 57.5.47        | Tx 512- to 1023-byte Packets Statistic Register (ENET_RMON_T_P512TO1023).....              | 2046 |
| 57.5.48        | Tx 1024- to 2047-byte Packets Statistic Register (ENET_RMON_T_P1024TO2047).....            | 2047 |
| 57.5.49        | Tx Packets Greater Than 2048 Bytes Statistic Register (ENET_RMON_T_P_GTE2048).....         | 2047 |
| 57.5.50        | Tx Octets Statistic Register (ENET_RMON_T_OCTETS).....                                     | 2047 |
| 57.5.51        | Reserved Statistic Register (ENET_IEEE_T_DROP).....                                        | 2048 |
| 57.5.52        | Frames Transmitted OK Statistic Register (ENET_IEEE_T_FRAME_OK).....                       | 2048 |
| 57.5.53        | Frames Transmitted with Single Collision Statistic Register (ENET_IEEE_T_1COL).....        | 2049 |
| 57.5.54        | Frames Transmitted with Multiple Collisions Statistic Register (ENET_IEEE_T_MCOL).....     | 2049 |
| 57.5.55        | Frames Transmitted after Deferral Delay Statistic Register (ENET_IEEE_T_DEF).....          | 2049 |
| 57.5.56        | Frames Transmitted with Late Collision Statistic Register (ENET_IEEE_T_LCOL).....          | 2050 |
| 57.5.57        | Frames Transmitted with Excessive Collisions Statistic Register (ENET_IEEE_T_EXCOL).....   | 2050 |
| 57.5.58        | Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET_IEEE_T_MACERR).....      | 2051 |

| Section number | Title                                                                                              | Page |
|----------------|----------------------------------------------------------------------------------------------------|------|
| 57.5.59        | Frames Transmitted with Carrier Sense Error Statistic Register (ENET_IEEE_T_CSERR).....            | 2051 |
| 57.5.60        | Reserved Statistic Register (ENET_IEEE_T_SQE).....                                                 | 2051 |
| 57.5.61        | Flow Control Pause Frames Transmitted Statistic Register (ENET_IEEE_T_FDXFC).....                  | 2052 |
| 57.5.62        | Octet Count for Frames Transmitted w/o Error Statistic Register (ENET_IEEE_T_OCTETS_OK).....       | 2052 |
| 57.5.63        | Rx Packet Count Statistic Register (ENET_RMON_R_PACKETS).....                                      | 2053 |
| 57.5.64        | Rx Broadcast Packets Statistic Register (ENET_RMON_R_BC_PKT).....                                  | 2053 |
| 57.5.65        | Rx Multicast Packets Statistic Register (ENET_RMON_R_MC_PKT).....                                  | 2053 |

# Chapter 1

## About This Manual

### 1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware. The manual describes the functionality of the superset device of the S32K1xx and S32K14xW series. For the available features, register implementation of a specific derivative (derivative device), please refer to the respective Chip-specific *module* information.

### 1.2 Organization

This manual has two main sets of chapters.

1. Chapters in the first set contain information that applies to all components on the chip.
2. Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

### 1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *Chip-specific [module name] information*, provides details such as the number of module instances on the chip and connections between the module and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

Figure 1-1. Example: chapter chip-specific information and general module information

### 1.3.1 Example: chip-specific information that clarifies content in the same chapter

The example below shows chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supercede the reset values that appear in the register diagram.

## Chapter 34 Software Watchdog Timer (SWT)

### 34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT\_A and SWT\_B.

#### 34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

| Register | SWT_A      | SWT_B      |
|----------|------------|------------|
| CR       | FF00_0100h | FF00_010Ah |
| TO       | 0005_FCD0h | 0005_FCD0h |

### 34.2 Introduction

This section provides an overview, list of features, and mode of operation for the SWT.

#### 34.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is also generated on a second consecutive time-out.

Sample Reference Manual

## Chapter 34 Software Watchdog Timer (SWT)

accesses by masters without permission. If the RIA bit in the SWT\_CR is set then the SWT generates a system reset on an invalid access otherwise a bus error is generated. If either the HLK or SLK bits in the SWT\_CR are set, then the SWT\_CR, SWT\_TO, SWT\_WN, and SWT\_SK registers are read-only.

The SWT memory map is shown in the following table.

| Address offset (hex) | Register name                        | Width (in bits) | Access | Reset value | Section/ page |
|----------------------|--------------------------------------|-----------------|--------|-------------|---------------|
| 0                    | Control Register (SWT_CR)            | 32              | RW     | See section | 34.4.1/1331   |
| 4                    | Interrupt Register (SWT_IR)          | 32              | RW     | 0000_0000h  | 34.4.2/1334   |
| 8                    | SWT Time-out Register (SWT_TO)       | 32              | RW     | See section | 34.4.3/1334   |
| 12                   | SWT Watchdog Register (SWT_WN)       | 32              | RW     | 0000_0000h  | 34.4.4/1335   |
| 16                   | SWT Service Register (SWT_SR)        | 32              | W      | 0000_0000h  | 34.4.5/1335   |
| 20                   | SWT Counter Output Register (SWT_CO) | 32              | R      | 0000_0000h  | 34.4.6/1336   |
| 24                   | SWT Service Register (SWT_SK)        | 32              | RW     | 0000_0000h  | 34.4.7/1336   |

#### 34.4.1 SWT Control Register (SWT\_CR)

##### NOTE

The reset value for the SWT\_CR is implementation specific. See the configuration information.

The SWT\_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT\_CR[HLK] or SWT\_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

| Bit   | 0    | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |  |  |

Figure 1-2. Example: chip-specific information that clarifies content in the same chapter

## 1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter.

Figure 1-3. Example: chip-specific information that refers to a different chapter

## 1.4 Register descriptions

Module chapters present register information in:

- Memory maps containing:
  - An offset from the module's base address
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)
  - Each register's reset value
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

Figure 1-4. Register figure conventions

## 1.5 Conventions

### 1.5.1 Notes, Cautions, and Warnings

Note, Caution, and Warning notices appear throughout this manual. Each notice type alerts readers to a specific kind of information.

#### NOTE

Notes convey information that may be tangential to a topic or that may not apply to all readers.

#### CAUTION

Caution notices call out information that readers should know before taking further action. Cautions frequently point to trouble spots that may damage the chip or board.

#### WARNING

Warning notices inform readers about actions that could result in unwanted consequences, especially those that may cause bodily injury.

### 1.5.2 Numbering systems

The following suffixes identify different numbering systems:

## Conventions

| This suffix | Identifies a                                                                                                                                                          |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b           | Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix <i>0b</i> .                |
| d           | Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.    |
| h           | Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix <i>0x</i> . |

### 1.5.3 Typographic notation

The following typographic notation is used throughout this document:

| Example               | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>placeholder, x</i> | Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.                                                                                                                                                                           |
| <code>code</code>     | Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.                                                                                          |
| SR[SCM]               | A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).                                                                                                                                                                                                                                                                   |
| REVNO[6:4], XAD[7:0]  | Numbers in brackets and separated by a colon represent either: <ul style="list-style-type: none"><li>• A subset of a register's named field<br/>For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.</li><li>• A continuous range of individual signals of a bus<br/>For example, XAD[7:0] refers to signals 7–0 of the XAD bus.</li></ul> |

### 1.5.4 Special terms

The following terms have special meanings:

| Term       | Meaning                                                                                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| asserted   | Refers to the state of a signal as follows: <ul style="list-style-type: none"><li>• An active-high signal is asserted when high (1).</li><li>• An active-low signal is asserted when low (0).</li></ul>                                                                               |
| deasserted | Refers to the state of a signal as follows: <ul style="list-style-type: none"><li>• An active-high signal is deasserted when low (0).</li><li>• An active-low signal is deasserted when high (1).</li></ul> <p>In some cases, deasserted signals are described as <i>negated</i>.</p> |

*Table continues on the next page...*

| Term     | Meaning                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reserved | Refers to a memory space, register, field, or programming setting. Device operation is not guaranteed when reserved locations are written to any value. <ul style="list-style-type: none"><li>• Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field.</li><li>• Consider undefined locations in memory to be reserved.</li></ul> |
| w1c      | Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."                                                                                                                                                                                                                                                                                                          |

# Chapter 2

## Introduction

### 2.1 Overview

The S32K1xx and S32K14xW product series further extends the highly scalable portfolio of Arm® Cortex®-M0+/M4F MCUs in the automotive industry. It builds on the legacy of the KEA series, while introducing higher memory options alongside a richer peripheral set extending capability into a variety of automotive applications. With a 2.70–5.5 V supply and focus on automotive environment robustness, the S32K product series devices are well suited to a wide range of applications in electrically harsh environments, and are optimized for cost-sensitive applications offering low pin-count options. The S32K product series offers a broad range of memory, peripherals, and package options. It shares common peripherals and pin counts, allowing developers to migrate easily within an MCU family or among the MCU families to take advantage of more memory or feature integration. This scalability allows developers to use the S32K product series as the standard for their end product platforms, maximizing hardware and software reuse and reducing time to market.

### 2.2 S32K1xx Series introduction

#### 2.2.1 S32K14x

S32K14x series of devices are 32-bit general purpose automotive microcontrollers based on the Arm Cortex-M4F core. They offer superior performance, large memories and the most scalable peripherals in this class. This product series provides up to 112 MHz CPU performance with DSP and FPU support, with up to 2 MB Flash and up to 256 KB SRAM. Overview of device features:

- 32-bit Arm Cortex-M4F core with FPU, up to 112 MHz (HSRUN) and 80 MHz (Normal RUN)

- Up to 2 MB code flash memory and 64 KB FlexMem (supports up to 4 KB emulated EEPROM<sup>1</sup> with 4 KB FlexRAM)
- Up to 256 KB SRAM supporting both CPU private access and crossbar access to provide parallel access of instruction and data
- Modified Harvard connections with Local Memory controller (LMEM) to support tightly coupled RAM and 4 KB Code Cache<sup>2</sup>
- Integrated clocking architecture with on-chip fast IRC 48-60 MHz, slow IRC 8 MHz / 2 MHz, 128 KHz LPO and a PLL unit
- Analog modules providing precision mixed-signal capabilities, including 12-bit up to two 1 Msps SAR ADC, high-speed comparator
- Power Management Controller (PMC) with internal regulators capable of supporting multiple power modes including:
  - HSRUN<sup>2, 3</sup>
  - RUN
  - STOP
  - VLPR
  - VLPS
- I/O supporting 2.7 V to 5.5 V supply
- Wide operating voltage ranges (2.7–5.5 V) with fully functional flash memory program/erase/read operations
- 48 LQFP, 64 LQFP, 100 LQFP, 144 LQFP, 176 LQFP and 100 MAPBGA packages with up to 156 GPIO pins
- Ambient operating temperature ranges from –40 °C to 125 °C<sup>3</sup>

The S32K14x MCU portfolio is supported by a highly comprehensive set of development tools and software. The enablement package includes: NXP Arduino compatible evaluation boards, S32K Software Development Kit (SDK) including graphical configurability and S32 Design Studio software, as well as broad support from IAR Systems, Arm, Software, Green Hills, and other partners.

---

1. CSEc (Security) or EEPROM writes/erase will trigger error flags in HSRUN mode (112 MHz) because this use case is not allowed to execute simultaneously. The device will need to switch to RUN mode (80 Mhz) to execute CSEc (Security) or EEPROM writes/erase.

2. This refers to region addressable by Arm CM4 Code bus and is used to cache code as well as data in this region. See S32K1xx\_memory\_map.xlsx for more details on cacheability of different regions.

3. HSRUN mode (112 MHz) operation is not valid at 125 °C.

## 2.2.2 S32K14xW

S32K14xW series of devices are 32-bit general purpose automotive micro-controllers based on the Arm Cortex-M4F core. They offer superior performance, large memories and the most scalable peripherals in this class. This product series provides up to 80 MHz CPU performance with DSP and FPU support, with up to 512 KB Flash and up to 64 KB SRAM. Overview of device features:

- 32-bit Arm Cortex-M4F core with FPU, up to 80 MHz
- Up to 512 KB code flash memory and 64 KB FlexMem (supports up to 4 KB emulated EEPROM with 4 KB FlexRAM)
- Up to 64 KB SRAM supporting both CPU private access and crossbar access to provide parallel access of instruction and data
- Modified Harvard connections with Local Memory controller (LMEM) to support tightly coupled RAM and 4 KB Code Cache<sup>4</sup>
- Integrated clocking architecture with on-chip fast IRC 48-60 MHz, slow IRC 8 MHz / 2 MHz, 128 KHz LPO and a PLL unit
- Analog modules providing precision mixed-signal capabilities, including 12-bit up to two 1 Msps SAR ADC, high-speed comparator
- Power Management Controller (PMC) with internal regulators capable of supporting multiple power modes including:
  - RUN
  - STOP
  - VLPR
  - VLPS
- I/O supporting 3.13 V to 5.5 V supply
- Wide operating voltage ranges (3.13–5.5 V) with fully functional flash memory program/erase/read operations
- 48 LQFP and 64 LQFP packages with up to 58 GPIO pins
- Ambient operating temperature ranges from –40 °C to 150 °C

The S32K14xW MCU portfolio is supported by a highly comprehensive set of development tools and software. The enablement package includes: NXP Arduino compatible evaluation boards, S32K Software Development Kit (SDK) including graphical configurability and S32 Design Studio software, as well as broad support from IAR Systems, Arm, Software, Green Hills, and other partners.

---

4. This refers to region addressable by Arm CM4 Code bus and is used to cache code as well as data in this region. See S32K1xx\_memory\_map.xlsx for more details on cacheability of different regions.

### 2.2.3 S32K11x

S32K11x series of devices are 32-bit general purpose automotive microcontrollers based on the Arm Cortex-M0+ core. They offer superior performance, large memories and the most scalable peripherals in this class. This product series provides 48 MHz CPU performance, with up to 256 KB Flash and up to 25 KB SRAM. Overview of device features:

- 32-bit Arm Cortex-M0+ core with 48 MHz CPU
- Up to 256 KB code flash memory and 32 KB FlexMem (supports up to 2 KB emulated EEPROM with 2 KB FlexRAM)
- Up to 25 KB SRAM
- Integrated clocking architecture with on-chip fast IRC 48 MHz, slow IRC 8MHz, and 128 KHz LPO
- Analog modules providing precision mixed-signal capabilities, including 12-bit 1 Msps SAR ADC, high-speed comparator
- Power Management Controller (PMC) with internal regulators capable of supporting multiple power modes including:
  - RUN
  - STOP
  - VLPR
  - VLPS
- I/O supporting 2.7 V to 5.5 V supply
- Wide operating voltage ranges (2.7–5.5 V) with fully functional flash memory program/erase/read operations
- 32-pin QFN, 48-pinLQFP, 64-pinLQFP with up to 58 GPIO pins
- Ambient operating temperature ranges from –40 °C to 125 °C

The S32K11x MCU portfolio is supported by a highly comprehensive set of development tools and software. The enablement package includes: NXP Arduino compatible evaluation boards, S32K Software Development Kit (SDK) including graphical configurability and S32 Design Studio software, as well as broad support from IAR Systems, Cosmic Software, Green Hills, and other partners.

## 2.3 Feature summary

The following table lists the features integrated on S32K1xx/S32K14xW product series.

**Table 2-1. Device feature summary**

| Feature | S32K11x product series | S32K14x product series | S32K14xW product series |
|---------|------------------------|------------------------|-------------------------|
|---------|------------------------|------------------------|-------------------------|

*Table continues on the next page...*

**Table 2-1. Device feature summary (continued)**

| Feature                                          | S32K11x product series                                                                                                | S32K14x product series                                                                                                                                                                                                                                            | S32K14xW product series                                                      |

| SAI                     | Not available                                                                                                                                                                                                                     | Supports full duplex serial interfaces with frame synchronization such as I2S, AC97, TDM, and codec/DSP interfaces. | Not available           |

1. HSRUN mode is limited to a maximum ambient temperature of 105°C T<sub>A</sub>
2. CSEc (Security) or EEPROM writes/erase will trigger error flags in HSRUN mode (112 MHz) because this use case is not allowed to execute simultaneously. The device need to switch to RUN mode (80 Mhz) to execute CSEc (Security) or EEPROM writes/erase.
3. On this device, NXP's system MPU implements the safety mechanisms to prevent masters from accessing restricted memory regions. This system MPU provides memory protection at the level of the Crossbar Switch. Each Crossbar master (Core, DMA, Ethernet) can be assigned different access rights to each protected memory region. The Arm M4 core version in this family does not integrate the Arm Core MPU, which would concurrently monitor only core-initiated memory accesses. In this document, the term MPU refers to NXP's system MPU.

## 2.4 Block diagram

The following figure shows block diagram of the S32K14x product series.

1: On this device, NXP's system MPU implements the safety mechanisms to prevent masters from accessing restricted memory regions. This system MPU provides memory protection at the level of the Crossbar Switch. Each Crossbar master (Core, DMA, Ethernet) can be assigned different access rights to each protected memory region. The Arm M4 core version in this family does not integrate the Arm Core MPU, which would concurrently monitor only core-initiated memory accesses. In this document, the term MPU refers to NXP's system MPU.

2: For the device-specific sizes, see the "On-chip SRAM sizes" table in the "Memories and Memory Interfaces" chapter of the S32K1xx Series Reference Manual.

3: CSEc (Security) or EEPROM writes/erase will trigger error flags in HSRUN mode (112 MHz) because this use case is not allowed to execute simultaneously. The device need to switch to RUN mode (80 MHz) to execute CSEc (Security) or EEPROM writes/erase.

## 2.5 Feature comparison

The following figure summarizes the memory, peripherals and packaging options for the S32K1xx and S32K14xW devices. All devices which share a common package are pin-to-pin compatible.

## NOTE

Availability of peripherals depends on the pin availability in a particular package. For more information see *IO Signal*

*Description Input Multiplexing sheet(s) attached with Reference Manual.*

## LEGEND:

○ Not implemented

● Available on the device

1 No write or erase access to Flash module, including Security (CSEc) and EEPROM commands, are allowed when device is running at HSRUN mode (112MHz) or VLPR mode.

2 Available when EEPROM, CSEc and Data Flash are not used. Else only up to 1,984 KB is available for Program Flash.

3 4 KB (up to 512 KB D-Flash as a part of 2 MB Flash). Up to 64 KB of flash is used as EEPROM backup and the remaining 448 KB of the last 512 KB block can be used as Data flash or Program flash. See chapter FTFC for details.

4 Only for Boundary Scan Register

5 See Dimensions section for package drawings

6 QuadSPI is not supported for S32K148 in 100-pin LQFP

**Figure 2-4. S32K14xW product series comparison**

## 2.5.1 Differences between S32K14x/S32K14xW, and S32K11x

Due to the differences in core and cache architecture between S32K11x and S32K14x/S32K14xW devices, their CPU execution and interrupt latency will be different which in turn will affect the observed time among the timers, and the associated events triggered by them. See [Arm Cortex-M4F Technical Reference Manual](#) and [Arm Cortex-M0+ Technical Reference Manual](#) for core architecture details. For more differences, see [AN11997](#), available at [nxp.com](#).

## 2.6 Applications

The S32K1xx product series are the ideal choices for general purpose automotive applications, which include but not limited to:

- Exterior and interior lighting
- HVAC
- Door/Window/Wiper/Seat controller
- BLDC/PMSM motor control
- Park assistant
- E-shifter
- TPMS
- Real time control in infotainment system
- Battery management system
- Human machine interface such as touch sense control
- Secured vehicle data transfer
- Safety controller
- Over the air update <sup>5</sup>

Moreover, the 100 Mbit IEEE-1588 Ethernet MAC and Serial audio interface (AC97, TDM, and I2S) on S32K148 make it fit perfectly for Ethernet connected edge nodes in vehicle, and the audio streaming application.

In addition to automotive applications, the S32K1xx product series can also be used in challenging environments found in industrial, automation, communications, transportation, medical and A & D applications which need high level quality, reliability and safety.

### NOTE

- For safety aware and critical application, the user must refer to S32K1xx Safety Manual and [Using the S32K1xx EEPROM Functionality](#) application note available on [nxp.com](#) for correct part operation requirements.
- See S32K1xx Safety Manual and [Production Flash Programming Best Practices for S32K1xx MCUs](#)

---

5. See [S32K Architecture and Capabilities to Enable Over the Air Updates](#)

application note available on [nxp.com](http://nxp.com) for correct part operation and memory handling during programming of the internal flash memory.

## 2.7 Module functional categories

The modules on this device are grouped into functional categories. The following sections describe the modules assigned to each category in more detail.

**Table 2-2. Module functional categories**

| Module category                       | Description                                                                                                                                                                                                                                                                                                                                                                                                               |

## 2.7.1 Arm® Cortex®-M4F Core Modules

The following core modules are available on this device.

**Table 2-3. Core modules**

| Module                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arm Cortex-M4F            | The Arm® Cortex®-M4F is the newest member of the Cortex M Series of processors targeting microcontroller cores focused on very cost sensitive, deterministic, interrupt driven environments. The Cortex M4F processor is based on the Armv7 Architecture and Thumb®-2 ISA and is upward compatible with the Cortex M3, Cortex M1, and Cortex M0 architectures. Cortex M4F improvements include an Armv7 Thumb-2 DSP (ported from the Armv7-A/R profile architectures) providing 32-bit instructions with SIMD (single instruction multiple data) DSP style multiply-accumulates and saturating arithmetic.                      |
| Floating point unit (FPU) | A single-precision floating point unit (FPU) that is compliant to the <i>IEEE Standard for Floating-Point Arithmetic</i> (IEEE 754).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| NVIC                      | <p>The Armv7-M exception model and nested-vector interrupt controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels.</p> <p>The NVIC replaces shadow registers with equivalent system and simplified programmability. The NVIC contains the address of the function to execute for a particular handler. The address is fetched via the instruction port allowing parallel register stacking and look-up. The first sixteen entries are allocated to Arm internal sources, with the others mapping to MCU-defined interrupts.</p> |
| AWIC                      | The primary function of the Asynchronous Wake-up Interrupt Controller (AWIC) is to detect asynchronous wake-up events in stop modes and then signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.                                                                                                                                                                                                                                                                                                       |
| Debug interfaces          | <p>Most of the debug capability on this device is based on the Arm CoreSight™ architecture. Following debug interfaces are supported:</p> <ul style="list-style-type: none"> <li>Serial wire IEEE 1149.1 JTAG debug Port (SWJ-DP), with 2 pin serial wire debug (SWD) for external debugger</li> <li>Debug Watchpoint and Trace (DWT), with four configurable comparators as hardware watchpoints</li> </ul>                                                                                                                                                                                                                    |

**Table 2-3. Core modules**

| Module | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | <ul style="list-style-type: none"> <li>Serial wire output (SWO)-synchronous trace data support</li> <li>Instrumentation Trace Macrocell (ITM) with software and hardware trace, plus time stamping</li> <li>Flash Patch and Breakpoints (FPB) with ability to patch code and data from code space to system space</li> <li>Serial Wire Viewer (SWV): A trace capability providing displays of reads, writes, exceptions, PC Samples and printf.</li> <li>Supports 4 pin trace interface</li> </ul> |

## 2.7.2 Arm Cortex-M0+ Core Modules

The following core modules are available on this device.

**Table 2-4. Core modules**

| Module                | Description                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arm Cortex-M0+        | The Arm® Cortex™-M0+processor is a configurable, multistage, 32-bit RISC processor. It has an AMBA AHB-Lite interface and includes an NVIC component. It also has optional hardware debug, single-cycle I/O interfacing, and memory-protection functionality. The processor can execute Thumb code and is compatible with other Cortex-M profile processors. |
| NVIC                  | <p>NVIC features up to 32 external interrupt inputs, each with four levels of priority. It implements optional relocation of the vector table.</p> <p>It features dedicated Non-Maskable Interrupt (NMI) input, supports optional Wake-up Interrupt Controller (WIC), providing ultra-low power sleep mode support.</p>                                      |
| AWIC                  | The primary function of the Asynchronous Wake-up Interrupt Controller (AWIC) is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.                                         |
| Single-cycle I/O Port | For high-speed, single-cycle access to peripherals, the Cortex-M0+ processor implements a dedicated single-cycle I/O port.                                                                                                                                                                                                                                   |
| Debug interfaces      | <p>Most of this device's debug is based on the Arm CoreSight™ architecture. One debug interfaces are supported:</p> <ul style="list-style-type: none"> <li>Serial Wire Debug (SWD)</li> <li>Micro Trace Buffer (MTB)</li> </ul>                                                                                                                              |

## 2.7.3 System modules

The following system modules are available on this device.

**Table 2-5. System modules**

| Module                                          | Description                                                                                                                                                                                                                                                 |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Miscellaneous control module (MCM)              | The MCM includes miscellaneous control logic for Core and System modules.                                                                                                                                                                                   |
| System integration module (SIM)                 | The SIM includes miscellaneous device configuration and status registers.                                                                                                                                                                                   |
| PORT                                            | The Port Control and Interrupt (PORT) module provides support for port control, digital filtering, and external interrupt functions.                                                                                                                        |
| GPIO                                            | The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface for maximum pin performance. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.                                             |
| Crossbar switch (AXBS-Lite)                     | The AXBS-Lite connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.                                                  |
| System Memory protection unit (MPU)             | The system MPU provides memory protection and task isolation. It concurrently monitors all bus master transactions for the slave connections.                                                                                                               |
| Peripheral bridge (AIPS-Lite)                   | The AIPS-Lite converts the crossbar switch interface to an interface that allows access to a majority of peripherals on the device.                                                                                                                         |
| Direct memory access multiplexer (DMAMUX)       | The DMAMUX selects from many DMA requests down to a smaller number for the DMA controller.                                                                                                                                                                  |
| enhanced Direct Memory Access controller (eDMA) | The eDMA provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-bit, 16-bit, 32-bit, 16-byte and 32-byte data values.                                                                          |
| TRGMUX                                          | The trigger multiplexer (TRGMUX) module allows software to configure the trigger sources for various peripherals.                                                                                                                                           |
| External watchdog monitor (EWM)                 | The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.                                                                                                             |
| Software watchdog (WDOG)                        | The WDOG monitors internal system operation and forces a reset in case of failure. It can run from an independent 128 kHz low power oscillator with a programmable refresh window to detect deviations in program flow or system frequency.                 |
| CRC                                             | Hardware CRC generator circuit using 16/32-bit shift register. Error detection for all single, double, odd, and most multi-bit errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register. |

## 2.7.4 Memories and memory interfaces

The following memories and memory interfaces are available on this device.

**Table 2-6. Memories and memory interfaces**

| Module                                     | Description                                                                                                                                                                                                                |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local memory controller(LMEM)              | Manages simultaneous accesses to system RAM by multiple master peripherals and core. Also provide cache control, which improves system performance by providing single-cycle access to the instruction and data pipelines. |
| Miscellaneous System Control Module (MSCM) | The Miscellaneous System Control Module (MSCM) contains CPU configuration registers and on-chip memory controller registers.                                                                                               |

*Table continues on the next page...*

**Table 2-6. Memories and memory interfaces (continued)**

| Module                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flash memory            | <ul style="list-style-type: none"> <li>• Program flash memory — non-volatile flash memory that can execute program code</li> <li>• FlexMemory — encompasses the following memory types: <ul style="list-style-type: none"> <li>• FlexNVM — Non-volatile flash memory that can execute program code, store data, or backup emulated EEPROM data</li> <li>• FlexRAM — RAM memory that can be used as traditional SRAM or as high-endurance emulated EEPROM storage, and also accelerates flash programming</li> </ul> </li> </ul> |
| QuadSPI                 | The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to external serial flash device. It supports SDR and HyperRAM modes up to 4 and 8 bidirectional data lines respectively.                                                                                                                                                                                                                                                                                                                              |
| Flash memory controller | Manages the interface between the device and the on-chip flash memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SRAM                    | Internal system RAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 2.7.5 Power Management

The following modules are available on this device for power management and system power modes control:

**Table 2-7. Power Management modules**

| Module | Description                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------|
| PMC    | The PMC contains the internal voltage regulator, power on reset (POR) and the low voltage detect (LVD) system.              |
| SMC    | The System Mode Controller (SMC) is responsible for sequencing the system into and out of all low-power Stop and Run modes. |

## 2.7.6 Clocking

The following clock modules are available on this device.

**Table 2-8. Clock modules**

| Module                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System clock generator (SCG) | <p>The SCG provides several clock sources for the MCU that include:</p> <ul style="list-style-type: none"> <li>• Phase-locked loop (PLL) — Voltage-controlled oscillator (VCO)</li> <li>• Fast internal reference clock (FIRC) — An internally-generated 48 MHz clock, which can be used as a clock source for other on-chip peripherals</li> <li>• Slow internal reference clock (SIRC) — An internally-generated 8 MHz clock, which can be used as a clock source for other on-chip peripherals</li> <li>• System oscillator (OSC) — The system oscillator, in conjunction with an external crystal or resonator, generates a reference clock for the MCU</li> </ul> |

*Table continues on the next page...*

**Table 2-8. Clock modules (continued)**

| Module                         | Description                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Low Power Oscillator (LPO)     | An internally-generated low power clock with typical frequency of 128 kHz, which can be used as clock source for modules operational in low power modes. |
| Peripheral Clock Control (PCC) | Controls the clock selection for most modules.                                                                                                           |

## 2.7.7 Analog modules

The following analog modules are available on this device:

**Table 2-9. Analog modules**

| Module                                              | Description                                                                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 12-bit analog-to-digital converters (ADC)           | 12-bit successive-approximation ADC                                                                                                 |
| Analog comparators (CMP)                            | Compares two analog input voltages across the full range of the supply voltage.                                                     |
| 8-bit digital-to-analog converters (DAC) within CMP | 256-tap resistor ladder network which provides a selectable voltage reference for applications where a voltage reference is needed. |

## 2.7.8 Timer modules

The following timer modules are available on this device:

**Table 2-10. Timer modules**

| Module                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Programmable delay block (PDB) | <ul style="list-style-type: none"> <li>• 16-bit resolution</li> <li>• 3-bit prescaler</li> <li>• Positive transition of trigger event signal initiates the counter</li> <li>• Supports multiple triggered delay output signals, each with an independently-controlled delay from the trigger event</li> <li>• Continuous-pulse output or single-shot mode supported, each output is independently enabled, with possible trigger events</li> <li>• Supports bypass mode</li> <li>• Supports DMA</li> </ul>                                                                                                                                                                         |
| Flexible timer module (FTM)    | <ul style="list-style-type: none"> <li>• Selectable FTM source clock, programmable prescaler</li> <li>• 16-bit counter supporting free-running or initial/final value, and counting is up or up-down</li> <li>• Input capture, output compare, and edge-aligned and center-aligned PWM modes</li> <li>• Operation of FTM channels as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs</li> <li>• Deadtime insertion is available for each complementary pair</li> <li>• Generation of hardware triggers</li> <li>• Software control of PWM outputs</li> <li>• Up to 4 fault inputs for global fault control</li> </ul> |

*Table continues on the next page...*

**Table 2-10. Timer modules (continued)**

| Module                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 2.7.9 Communication interfaces

The following communication interfaces are available on this device:

**Table 2-11. Communication modules**

| Module                                                          | Description                                                                                                                                                                                         |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Low-power Serial peripheral interface (LPSPi)                   | Synchronous serial bus for communication to an external device. LPSPi optionally remains functional in low power modes.                                                                             |
| Low-power Inter-integrated circuit (LPI2C)                      | Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2. LPI2C optionally remains functional in low power modes.                 |
| Low-power Universal asynchronous receiver/transmitters (LPUART) | Asynchronous serial bus communication interface, supporting LIN master and slave operation. LPUART optionally remains functional in low power modes.                                                |
| SAI/I2S                                                         | The I2S (or I2S) module provides a synchronous audio interface (SAI) that supports full duplex serial interfaces with frame synchronization such as I2S, AC97, TDM, and codec/DSP interfaces.       |
| ENET                                                            | The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full duplex 10/100-Mbit/s Ethernet LANs. |
| FlexCAN                                                         | The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications.                                         |

## 2.7.10 Debug modules

The following Debug modules are available on this device:

**Table 2-12. Debug modules**

| Module | Description                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JTAGC  | The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. |

## Chapter 3 Memory Map

### 3.1 Introduction

This chip contains various memories and memory-mapped peripherals that are located in one 32-bit contiguous memory space. This chapter describes the memory and peripheral locations within that memory space.

Details about the memory map appear in the spreadsheet that is attached to this document: S32K1xx\_memory\_map.xlsx. To access this spreadsheet, view the document's list of attachments.

### 3.2 SRAM memory map

#### 3.2.1 S32K14x: SRAM memory map

The on-chip RAM is split in two regions: SRAM\_L and SRAM\_U. The RAM is implemented such that the SRAM\_L and SRAM\_U ranges form a contiguous block in the memory map. See S32K1xx\_memory\_map.xlsx attached to this document for details.

Accesses to the SRAM\_L and SRAM\_U memory ranges outside the amount of RAM on the chip causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master.

#### 3.2.2 S32K11x: SRAM memory map

In S32K11x on-chip RAM can be used in following applications:

- Safety critical applications: SRAM\_U can be used, which starts from 2000\_0000
- Non-safety critical applications: SRAM\_U along with 1 KB MTB can be used

NOTE

CM0+ architecture implements single RAM controller, hence SRAM\_U and MTB are referred as single contiguous memory regions. MTB in S32K11x is present at the same location as SRAM\_L in S32K14x.

See S32K1xx\_memory\_map.xlsx attached to this document for details. Accesses to the memory ranges outside the amount of RAM on the chip causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master.

3.3 Flash memory map

The various flash memories and the flash memory registers are located at different base addresses as shown in the following figure. The base address for each is specified in the S32K1xx\_memory\_map.xlsx file attached to this document.

Figure 3-1. Flash memory map

3.4 Peripheral bridge (AIPS-Lite) memory map

The peripheral memory map is accessible via a crossbar slave port. There are three regions associated with peripheral space, as shown in the following table.

**Table 3-1. Regions associated with peripheral space**

| Address space           | Region description                                                                                                                                                                                                                                                                                                             |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x4000_0000–0x4001_FFFF | A 128 KB region, partitioned as 32 spaces, each 4 KB in size and reserved for on-platform peripheral devices. AIPS-Lite generates unique module enables for all 32 spaces.                                                                                                                                                     |
| 0x4002_0000–0x4007_FFFF | A 384 KB region, partitioned as 96 spaces, each 4 KB in size and reserved for off-platform modules. AIPS-Lite generates unique module enables for all 96 spaces.                                                                                                                                                               |
| 0x400F_F000             | A 4 KB region for accessing the GPIO module. This block is connected to the AMBA bus via the port splitter and provides direct master access without incurring wait states associated with accesses via the AIPS-Lite modules. The GPIO is implemented only in the upper space of this region (4 KB beginning at 0x400F_F000). |

Modules that are disabled via their clock gate control bits in the PCC/SIM registers disable the associated AIPS-Lite slots. Access to any address within an unimplemented or disabled peripheral bridge slot results in a transfer error termination.

### NOTE

While trying to access memory map region of unavailable feature (See SIM\_SDID[FEATURES]) with corresponding module clock enabled through PCC CGC bit, there will not be any transfer error termination.

## 3.4.1 Read-after-write sequence and required serialization of memory operations

In some situations, a write to a peripheral must be completed fully before a subsequent action can occur. Examples of such situations include:

- Exiting an interrupt service routine (ISR)
- Changing a mode
- Configuring a function

In these situations, the application software must perform a read-after-write sequence to guarantee the required serialization of the memory operations, as shown in the following table.

**Table 3-2. Read-after-write sequence to guarantee required serialization of memory operations**

| Step | Action                                                    |
|------|-----------------------------------------------------------|
| 1    | Write the peripheral register.                            |
| 2    | Read the written peripheral register to verify the write. |
| 3    | Continue with subsequent operations.                      |

**NOTE**

In S32K14x series of devices, one factor contributing to these situations is processor write buffering. The processor architecture has a programmable configuration field to disable write buffering: ACTLR[DISDEFWBUF]. (For details see Arm® Cortex® M4 Processor Technical Reference Manual, Revision r0p1, at <http://arm.com> ). However, disabling buffered writes is likely to degrade system performance much more than simply performing the required memory serialization for the situations that truly require it.

### 3.5 Private Peripheral Bus (PPB) memory map

The PPB is part of the defined Arm bus architecture and provides access to select processor-local modules. These resources are only accessible from the core; other system masters do not have access to them.

**Table 3-3. PPB memory map for CM4**

| System 32-bit address range | Resource                                                                    |
|-----------------------------|-----------------------------------------------------------------------------|
| 0xE000_0000–0xE000_0FFF     | Instrumentation Trace Macrocell (ITM)                                       |
| 0xE000_1000–0xE000_1FFF     | Data Watchpoint and Trace (DWT)                                             |
| 0xE000_2000–0xE000_2FFF     | Flash Patch and Breakpoint (FPB)                                            |
| 0xE000_3000–0xE000_DFFF     | Reserved                                                                    |
| 0xE000_E000–0xE000_EFFF     | System Control Space (SCS) (for NVIC and FPU)                               |
| 0xE000_F000–0xE003_FFFF     | Reserved                                                                    |
| 0xE004_0000–0xE004_0FFF     | Trace Port Interface Unit (TPIU)                                            |
| 0xE004_1000–0xE004_1FFF     | Reserved                                                                    |
| 0xE004_2000–0xE004_2FFF     | Reserved                                                                    |
| 0xE004_3000–0xE004_3FFF     | Reserved                                                                    |
| 0xE004_4000–0xE007_FFFF     | Reserved                                                                    |
| 0xE008_0000–0xE008_0FFF     | Miscellaneous Control Module (MCM)                                          |
| 0xE008_1000–0xE008_1FFF     | Reserved                                                                    |
| 0xE008_2000–0xE008_2FFF     | Cache Controller (LMEM)                                                     |
| 0xE008_3000–0xE00F_EFFF     | Reserved                                                                    |
| 0xE00F_F000–0xE00F_FFFF     | Arm Core ROM Table <sup>1</sup> - allows auto-detection of debug components |

1. The Arm Core ROM table is optionally required by Arm CoreSight debug infrastructure to discover the components on the chip. This ROM table has no any relationship with the MCU Boot ROM.

**Table 3-4. PPB memory map for CM0+**

| System 32-bit address range | Resource                              |
|-----------------------------|---------------------------------------|
| 0xE000_0000–0xE000_0FFF     | Reserved <sup>1</sup>                 |
| 0xE000_1000–0xE000_1FFF     | Data Watchpoint and Trace (DWT)       |
| 0xE000_2000–0xE000_2FFF     | Arm Core ROM Table                    |
| 0xE000_3000–0xE000_DFFF     | Reserved <sup>1</sup>                 |
| 0xE000_E000–0xE000_EFFF     | System Control Space (SCS) (for NVIC) |
| 0xE000_F000–0xE003_FFFF     | Reserved <sup>1</sup>                 |
| 0xE004_0000–0xE004_0FFF     | Reserved <sup>1</sup>                 |
| 0xE004_1000–0xE004_1FFF     | Reserved <sup>1</sup>                 |
| 0xE004_2000–0xE004_2FFF     | Reserved <sup>1</sup>                 |
| 0xE004_3000–0xE004_3FFF     | Reserved <sup>1</sup>                 |
| 0xE004_4000–0xE007_FFFF     | Reserved <sup>1</sup>                 |
| 0xE008_0000–0xE008_0FFF     | Reserved <sup>1</sup>                 |
| 0xE008_1000–0xE008_1FFF     | Reserved <sup>1</sup>                 |
| 0xE008_2000–0xE008_2FFF     | Reserved <sup>1</sup>                 |
| 0xE008_3000–0xE00F_EFFF     | Reserved <sup>1</sup>                 |
| 0xE00F_F000–0xE00F_FFFF     | Reserved <sup>1</sup>                 |
| 0xE010_0000–0xEFFF_FFFF     | Reserved <sup>1</sup>                 |

1. Reserved area return transfer error. Reserved is Unknown/Should be 0. Software must not rely on reading as all 0s, and it must treat the value as if it is unknown.

## 3.6 Aliased bit-band regions for CM4 core

The SRAM\_U, AIPS-Lite, and general purpose input/output (GPIO) module resources reside in the Cortex-M4F processor bit-band regions.

The processor also includes two 32 MB aliased bit-band regions associated with the two 1 MB bit-band spaces. Each 32-bit location in the 32 MB space maps to an individual bit in the bit-band region. A 32-bit write in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

Bit 0 of the value written to the alias region determines what value is written to the target bit:

- Writing a value with bit 0 set writes a 1 to the target bit.
- Writing a value with bit 0 clear writes a 0 to the target bit.

A 32-bit read in the alias region returns either:

- a value of 0x0000\_0000 to indicate the target bit is clear
- a value of 0x0000\_0001 to indicate the target bit is set

**Figure 3-2. Alias bit-band mapping**

**NOTE**

Each bit in a bit-band region has an equivalent bit that can be manipulated through bit 0 in a corresponding long word in the alias bit-band region.

**NOTE**

Do not use bit banding for wlc status bits.

**CAUTION**

The S32K product series and the software drivers support bit-banding, but Arm no longer promotes its usage. Therefore, we recommend that bit-banding should not be used.

## Chapter 4

# Signal Multiplexing and Pin Assignment

### 4.1 Introduction

The signal multiplexing enables the sharing of single pad for multiple functions.

The signal multiplexing unit comprises of control signals from [GPIO](#), [PORT](#) and pad interface logic. The signal multiplexing unit consists of several individual sub-units, each handling the signal multiplexing of one pad.

The Port Control block controls the module specific pad settings (pull up etc) and the signal present on the external pin. See [PORT\\_PCR](#) for the description of control signals. For reset values per port, see IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual.

### 4.2 Functional description

The signal multiplexing architectural implementation is as shown in the following figure.

Figure 4-1. Signal Multiplexing

### 4.3 Pad description

Following figure shows the basic representation of a GPIO Pad.

Figure 4-2. GPIO pad representation

Table 4-1. Pad Signal description

| Signal name | Direction | Description                                                                                         |
|-------------|-----------|-----------------------------------------------------------------------------------------------------|
| pad         | I/O       | I/O to external world                                                                               |
| do          | I         | Data coming from the core into the pad                                                              |
| obe         | I         | Enable output driver                                                                                |
| pue         | I         | 0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor      |
| pus         | I         | 0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set |
| ibe         | I         | Enable input receiver                                                                               |
| ind         | O         | Data coming out of the pad into the core                                                            |

**Table 4-2. Truth table**

| obe | do  | pad | Description                                                   |
|-----|-----|-----|---------------------------------------------------------------|
| 0   | X   | Z   | Output buffer disabled, pad hi-Z (If not configured as input) |
| 1   | 0/1 | 0/1 | Output buffer enable, pad = do                                |

| pue | pus | pad | Description                                    |
|-----|-----|-----|------------------------------------------------|
| 0   | 0/1 | -   | Weak pull disabled. Pad retains previous state |
| 1   | 0   | 0   | Weak pull down enabled                         |
| 1   | 1   | 1   | Weak pull up enabled                           |

| ibe | pad | ind | Description                         |
|-----|-----|-----|-------------------------------------|
| 0   | X   | 0   | Input buffer disabled, ind gets low |
| 1   | 0/1 | 0/1 | Input buffer enabled, ind = pad     |

**NOTE**

The device does not support open drain on all the pins. Only pins that are configured for a protocol that requires open-drain (e.g., LPI2C, LPUART single-wire) will work in open-drain mode.

**4.4 Default pad state**

The default pad configurations out of reset are as follows. For PTA4, PTA5, PTC4 and PTC5, the default configurations are as per protocol specifications/requirements.

**Table 4-3. Default pad configurations**

| Pin               | Default function | Default pad state <sup>1</sup> | ibe | obe | pue | pus |
|-------------------|------------------|--------------------------------|-----|-----|-----|-----|
| PTA4              | JTAG_TMS         | Weak pull-up enabled           | 1   | 0   | 1   | 1   |
| PTA5 <sup>2</sup> | RESET_b          | Weak pull-up enabled           | 1   | 0   | 1   | 1   |
| PTC4              | JTAG_TCK         | Weak pull-down enabled         | 1   | 0   | 1   | 0   |
| PTC5              | JTAG_TDI         | Weak pull-up enabled           | 1   | 0   | 1   | 1   |
| Others            | Disabled         | High impedance                 | 0   | 0   | 0   | 0   |

IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual contains information on pins/balls of this device.

The 'IO Signal Table' and 'Input Muxing' tabs in the sheet correspond to the signal multiplexing information. The 'IO Signal Table' consists of all the pin muxing details and the 'Input Muxing' specifies the priority for the input muxing where an input path is driven by more than one pad.

S32K1xx variant specific IO Signal Description Input Multiplexing sheets attached to the Reference Manual contains information about the pins/balls of the particular variant. Module functionality is dependent on the availability of functional pins in a particular package. For example LPI2C HREQ pin is not available in 48-LQFP and 32-QFN package.

Following is an example snippet of IO Signal Table. For selecting any functionality, the pad PCR register (refer to PORT\_PCRn) needs to be configured accordingly.

[illegible]

### Figure 4-3. IO signal table snippet

The columns of the above figure are described below:

- **Port:** This field in IO Signal Table specifies the PAD names of the device.
- **CR(Control Register):** This field specifies the name of PCR corresponding to the Port field. On this device there are five PORT instances, namely, PTA, PTB, PTC, PTD and PTE. Each pad has a corresponding Control Register, referred to as PCR\_PTXn

in the IO Signal Table, where X refers to PORT instance and n refers to corresponding pin of that PORT instance. Refer PORT\_PCR for description of PCR fields.

- SSS: This field specifies the ALT mode of operation as per PCR[Mux\_mode]. Not all pins support all pin muxing slots. Unimplemented pin muxing slots are reserved. The corresponding pin is configured in the following pin muxing slot as follows:
  - 000: Alternative 0 (Signal path disabled)
  - 001: Alternative 1 (GPIO)
  - 010: Alternative 2 (chip-specific)
  - 011: Alternative 3 (chip-specific)
  - 100: Alternative 4 (chip-specific)
  - 101: Alternative 5 (chip-specific)
  - 110: Alternative 6 (chip-specific)
  - 111: Alternative 7 (chip-specific)

The analog functionalities are specified with '-' in this field. Here ADC\_SE0 and CMP\_IN0 represent analog functions.

By default, ALT0 mode (configured by PTXn\_PCR[SSS] as 3'b000) corresponds to disabled functionality and pad represents disabled (high-impedance) state. In case if the pad consists of analog functions, the ALT0 mode corresponds to analog functionality once the analog module is configured to enable corresponding channel/input.

For example, PTA0 supports ADC0 channel 0 and CMP channel 0. By default the pad is disabled. After ADC0 is configured to enable channel0 using ADC0\_SC1n[ADCH], the pad functions as ADC input channel. Alternatively if CMP is configured to enable channel 0 using CMP\_C1[PSEL] or CMP\_C1[MSEL], the pad functions as CMP input channel. The software must ensure to enable only one function at a time.

- Function: This field specifies the functionality of the pad as per the corresponding ALT mode specified by SSS field.
- Module: The Module field contains the module which is governing the pad for the ALT mode.
- Description: This field mentions a short description of pad functionality.
- Direction: This field specifies the direction (Input, Output or Inout) of the pad for the concerned functionality.
- The next columns specify the pin number in the supported packages for the device.
- PCR: This field specifies the default PCR value for corresponding pad. Refer PORT\_PCR for description of PCR fields.

- The next two columns specify the reset value and the configurable bit fields of PCR corresponding to pad.
- Pad Type: This field mentions the pad type of the corresponding pad.
  - GPIO: General Purpose IO Pad (Standard)
  - GPIO-HD: General Purpose IO Pad that support high drive functionality (Strong)
  - GPIO-FAST: General Purpose IO Pad that support High Speed (applicable for S32K148 only)

### NOTE

If oscillator is enabled then enabling the GPIO or LPI2C function for EXTAL/XTAL pins can lead to device damage. This must be avoided by software.

## 4.5.2 Input muxing table

As the same function can be multiplexed to several pads by configuring their respective PCRs, there is priority input muxing. In case of same input being driven from multiple pads, the one with highest priority (1 being the highest) will drive the input. Following is a snippet of Input Muxing Table.

| Destination Instance | Destination Function | Priority | SSS       | Source Instance | Source Signal |
|----------------------|----------------------|----------|-----------|-----------------|---------------|
| CAN0                 | CAN0_RX              | 1        | 0000_0011 | IO_PAD          | PTC2          |
|                      |                      | 2        | 0000_0101 | IO_PAD          | PTE4          |
|                      |                      | 3        | 0000_0101 | IO_PAD          | PTB0          |
|                      |                      | 4        |           | -               | disable low   |

**Figure 4-4. Input muxing table snippet**

The columns of the figure are briefly described below:

- Destination Instance: This field contains the instance name of the input path to where the signal will propagate from padding.
- Destination Function: This field mentions the function name of the input path.
- Priority: This field specifies the priority of the path. Priority level 1 is highest and it decreases onwards.
- SSS: This field specifies the PCR[Mux\_mode] value corresponding to the pad specified in source signal column. A blank is mentioned for the default source when none pad is driving the input path.
- Source Instance: This field specifies the source pad type. A blank is mentioned for the default source when none pad is driving the input path.
- Source Signal: This field mentions the pad name. A 'disable low'/'disable high' specifies the signal behavior when none of the pads are driving the input path.

## 4.6 Pinout diagrams

See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for pinout diagrams corresponding to available packages.

# Chapter 5

## Security Overview

### 5.1 Introduction

All chips of this S32K1xx product series have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access.

### 5.2 Device security

Flash memory security is available to both CSEc and non-CSEc parts. [SIM\\_SDID\[7\]](#) indicates whether CSEc is available on your device.

Both CSEc and non CSEc users need to run PGMPART command to configure the Key Size for the device. For more information, see [Program Partition command](#). This process involves configuring a number of user keys. For non CSEc users, Key Size will be 00.

- The total size of EEERAM is reduced by the space required to store the user keys. (See [Introduction](#) chapter for available EEERAM.)
- The user key space effectively becomes un-addressable space in the EEERAM.
- For non-CSEc parts and CSEc parts with key size=00, [CSEc\\_PRAM](#) access is not guaranteed.

#### 5.2.1 Flash memory security

The flash memory module provides security information to the MCU based on the state held by the FSEC[SEC] field. The MCU, in turn, confirms the security request and limits access to flash memory resources. During reset, the flash memory module initializes the FSEC register using data read from the security byte of the flash memory configuration field.

**NOTE**

The security features apply only to external accesses via debug. CPU accesses to the flash memory are not affected by the status of FSEC.

In the unsecured state, all flash memory commands are available to the programming interfaces (SWD (Serial Wire Debug) and JTAG (Joint Test Access Group)), as are user code execution of Flash Memory Controller commands. When the flash memory is secured (FSEC[SEC] = 00b, 01b, or 11b), programmer interfaces are allowed to launch only mass erase operations and have no access to memory locations.

Further information regarding the flash memory security options and enabling/disabling flash security is available in the [Flash Memory Module](#).

**5.2.1.1 Flash memory security interactions with debug**

When flash memory security is active, the JTAG port cannot access the memory resources of the MCU. Boundary scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read flash memory contents.

When flash memory security is active, the SWD port cannot access the memory resources of the MCU.

Although most debug functions are disabled, the debugger can write to the Flash Mass Erase in Progress bit in the MDM-AP Control register to trigger a mass erase (Erase All Blocks) command provided that MEEN (mass erase) is enabled. Running the mass erase de-asserts the FSEC and after that JTAG port can access the memory resources. A mass erase via the debugger is allowed even when some memory locations are protected.

When mass erase is disabled, mass erase via the debugger is blocked. Hence, you will not be able to connect the debugger in a secure device (MEEN disabled). An alternative in that case would be to run verify backdoor key access through any communication interface.

The FTFC\_FCSESTAT[EDB] bit clear status is as follows:

- If the debugger has switched to SWD mode, the FTFC\_FCSESTAT[EDB] bit can be reset only through POR.
- If the debugger remains in JTAG mode, the FTFC\_FCSESTAT[EDB] bit is reset on pin\_reset if correct debugger disconnection takes place or on POR.

## 5.2.2 Cryptographic Services Engine (CSEc) security features

The FTFC module's [Cryptographic Services Engine \(CSEc\)](#) implements a comprehensive set of cryptographic functions as described in the SHE Functional Specification, including:

- >10 general purpose keys
- AES-128, CBC, ECB, CMAC
- Sequential, Parallel, and Strict Boot mode
- AES-128 CMAC calculation and authentication
- Pseudo random number generation (PRNG) and true random number generation (TRNG)

## 5.2.3 Device Boot modes

In parallel secure boot mode, secure boot and application boot shall happen in parallel. Also even if the secure boot fails, the application shall boot. But Keys having BOOT\_PROT attribute set to one, would be disabled. Application can make use of rest of the keys and encryption/decryption/SHE functions. However, application code should poll the Busy Flag FCSESTAT[BSY] , before attempting to actuate any SHE command. Additionally, during parallel secure boot, any mode transition initiated by Core will be aborted and secure boot will proceed.

During parallel boot operation FLASH\_CLK must be the default FIRC\_CLK and should not be changed until boot operation is complete. Once the boot operation is complete it can be changed to any value including its maximum value of 26.6 MHz in RUN mode and 28 MHz in HSRUN mode.

In Sequential Secure boot, Application shall boot only after successful completion of Secure boot. And, Application can actuate any command without bothering for FCSESTAT[BSY] flag. However, in Strict boot mode, the chip will not boot at all and will remain stuck in reset, if secure boot fails.

## 5.3 Security use case examples

### 5.3.1 Secure boot: check bootloader for integrity and authenticity

The following diagram illustrates a use case for detecting and preventing bootloader modification.

**Figure 5-1. Bootloader integrity and authenticity**

The MAC protects against modification of the bootloader and depends on the (secret) boot key.

Only if the calculated MAC value matches the stored boot MAC value: a successful secure boot occurs, and keys become unlocked for further use.

### 5.3.2 Chain of trust: check flash memory for integrity and authenticity

In this use case:

- The bootloader is protected by the secure boot process.
- MACs stored in the bootloader provide integrity and authenticity of the related parts in flash memory.
- Part-by-part checking of flash memory ensures each part's integrity and authenticity before executing it. Critical parts of flash memory (for example, MCU configuration/IRQ table) are checked and then executed as soon as possible.

**Figure 5-2. Flash memory integrity and authenticity**

### 5.3.3 Secure communication

This use case demonstrates how to prevent illegal messages sent by ECUs.

- Random number generation and checking protect against replay attacks.
- Encryption protects against eavesdropping.
- Random number generation/checking and encryption ensure data integrity and authenticity.

Figure 5-3. Secure communication

### 5.3.4 Component protection

The replacement or modification of ECU <n> will change its unique ID and/or keys. This use case shows how both changes are detected.

Figure 5-4. Component protection

### 5.3.5 Message-authentication example

This use case consists of an Rx-CAN message authentication scenario:

1. CAN data stored in local buffer
2. FlexCAN triggers interrupt to core/DMA
3. Transfer data to CSEc memory (maximum 12 CAN messages of 8 bytes + 16-byte CMAC)
4. Trigger CSEc CMAC calculation/verification
5. CSEc triggers interrupt to core
6. Core reads processed message data

Figure 5-5. Message authentication

## 5.4 Steps required before failure analysis

Before returning a device to NXP for failure analysis, the user must run the [CMD\\_DBG\\_CHAL](#) and [CMD\\_DBG\\_AUTH](#) commands and ensure that all keys stored in NVM memory are deleted. This is a mandatory step to enable failure analysis at NXP.

**NOTE**

If WRITE\_PROTECTION flag is set for any key then the user will be unable to delete that key with DEBUG\_CHAL and DEBUG\_AUTH commands and failure analysis would not be possible.

**5.5 Security programming flow example (Secure Boot)**

1. Run PGMPART to configure desired number of keys and other parameters
2. Program code section in Pflash to be checked in secure boot
3. LOAD\_KEY(BOOT\_MAC\_KEY)
4. CMD\_BOOT\_DEFINE to select the flavor of boot and size of data to validate in Pflash

Then optionally reset the part to "auto calculate" and program the BOOT\_MAC or the user loads the BOOT\_MAC by external calculation.

# Chapter 6

## Safety Overview

### 6.1 Introduction

The S32K1xx series is developed according to ISO 26262 and has an integrated safety concept targeting an ISO26262 ASIL-B integrity level. The following documentation supports the integration of an S32K1xx chip into safety-related systems:

- Reference Manual (S32K1XXRM): describes the programming model and functionality of S32K1xx chips
- Data Sheet (S32K1XX): describes S32K1xx operating conditions as well as timing and electrical characteristics
- Safety Manual (S32K1XXSM): describes the S32K1xx safety concept and possible safety mechanisms (integrated in S32K1xx, system-level hardware, or system-level software) as well as measures to reduce dependent failures
- Dynamic FMEDA: inductive analysis enabling customization of system-level safety mechanisms, including the resulting safety metrics for ISO 26262 (SPFM, LFM & PMHF) and IEC 61508 (SFF & Beta IC Factor)
- FMEDA Report: describes the FMEDA methodology and safety mechanisms supported in the FMEDA, including source of failure rates, failure modes, and assumptions during the analysis

The S32K1xx series is a SafeAssure™ solution. For more information regarding functional safety at NXP, visit <http://www.nxp.com/safeassure>.

**Figure 6-1. Functional safety overview**

## 6.2 S32K1xx safety concept

The S32K1xx series has an integrated safety concept targeting safety-related systems that require an ASIL-B safety integrity level. In general, safety integrity is achieved by using and applying S32K1xx safety features as described in the Safety Manual.

The following diagram provides an overview of integrated S32K1xx architecture and safety features.

Figure 6-2. S32K1xx safety block diagram

## 6.2.1 Cortex-M4/M0+ Structural Core Self Test (SCST)

Cortex-M4/M0+ Structural Core Self Test (SCST) is a software product from NXP. It was developed for detecting hardware permanent faults in a core by executing machine opcodes with a fixed set of operands and comparing their execution results. This library is considered a Safety Element out of context and was developed according to ASIL-B.

The SCST delivery contains the SCST library, a quality package, and a safety package.

- The quality package contains code coverage analysis, a MISRA report, a software requirements specification, and a Test Specification.
- The safety package consists of the SCST fault coverage estimation, the Safety Analysis and Concept, and the SCST Safety Manual.

The Safety Manual for Structural Core Self Test Library contains a list of recommendations and assumptions that should be fulfilled and verified by a user for the proper use of the SCST library for a Cortex-M4/M0+ core.

## 6.2.2 ECC on RAM and flash memory

Error correcting codes are used to protect transfers from a CPU core to flash memory and from a CPU core to system memory. Error Correcting Code (ECC) is implemented with Single-Error Correction, Double-Error Detection (SECDED).

References:

- Functional description: in this Reference Manual, see [MCM](#), [EIM](#), [ERM](#), [LMEM](#), and [FTFC](#)
- ECC on RAM and flash memory in safety concept: see Safety Manual

## 6.2.3 Power supply monitoring

S32K1xx includes a system for managing low-voltage conditions to protect memory contents and control MCU system states during supply voltage variations.

- Power-on reset (POR)
- Low-voltage detection (LVD)

References:

- Functional description: in this Reference Manual, see [Power Management](#)
- Power supply monitoring in safety concept: see Safety Manual chapter

## 6.2.4 Clock monitoring

Clocks in the S32K1xx are supervised by clock monitor units.

- System PLL clock monitor<sup>1</sup> : monitors the loss of PLL clock
- System Oscillator (SOSC) clock monitor<sup>2</sup> : monitors the loss of oscillator clock
- CMU monitor<sup>3</sup> FIRC clock for:
  - Loss of clock
  - Out of high and low range

References:

- Functional description: in this Reference Manual, see [Clock Distribution](#)
- Clock monitoring in safety concept: see Safety Manual chapter

## 6.2.5 Temporal protection

In a safety concept, watchdog timers provide temporal protection and monitor the operation of the system by expecting periodic communication from the software.

S32K1xx offers two watchdog timers:

- Watchdog timer (WDOG)<sup>4</sup> : An independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop.
- External Watchdog Monitor (EWM)<sup>5</sup> : A redundant watchdog system for safety. The EWM provides an independent output signal. It does not reset the MCU and peripherals.

References:

- Functional description: in this Reference Manual, see [WDOG](#) and [EWM](#)
- Temporal protection in safety concept: see Safety Manual chapter

## 6.2.6 Operational interference protection

S32K1xx provides safety mechanisms to:

- 
1. Available in S32K14x variants only
  2. Available in all S32K1xx variants
  3. Available in S32K11x only
  4. Available in all S32K1xx variants
  5. Available in S32K14x variants only

- prevent non-safety masters from interfering with the operation of the Safety Core
- manage the concurrent execution of software with different (lower) ASIL

A hierarchical memory protection scheme, which includes the following, protects against interference:

- System Memory Protection Unit (MPU)
- Peripheral Bridge (AIPS-Lite)
- Register protection

### 6.2.6.1 System Memory Protection Unit (MPU)

For ASIL-B applications, the system Memory Protection Unit (MPU) is used for execution control. It assigns access rights and ensures that only authorized software tasks can configure modules and access their allocated resources.

- The system MPU<sup>6</sup> provides memory protection at the Crossbar Switch. It splits the physical memory into 16 different regions.
- Each XBAR master (core, DMA, Ethernet) can be assigned different access rights to each region.
- The system MPU can be used to prevent non-safety masters (including DMA or Ethernet Controller) from accessing restricted memory regions.

References:

- Functional description: in this Reference Manual, see [MPU](#)
- MPU in safety concept: see Safety Manual chapter

### 6.2.6.2 Peripheral protection

Peripheral protection is based on the Peripheral Bridge (AIPS-Lite) module. It provides memory protection functionality by defining bus masters' access rights to various peripherals on the chip.

References:

- Functional description: in this Reference Manual, see [AIPS-Lite](#)
- Peripheral protection in safety concept: see Safety Manual chapter

---

6. On this device, NXP's system MPU implements the safety mechanisms to prevent masters from accessing restricted memory regions. This system MPU provides memory protection at the level of the Crossbar Switch. Each Crossbar master (Core, DMA, Ethernet) can be assigned different access rights to each protected memory region. The Arm M4 core version in this family does not integrate the Arm Core MPU, which would concurrently monitor only core-initiated memory accesses. In this document, the term MPU refers to NXP's system MPU.

### 6.2.6.3 Register protection

S32K1xx offers register protection for safety-critical registers. This protection is based on CPU program execution mode—User vs. Supervisor (privileged) mode—as well as another type of access restriction based on a lock feature implemented for certain registers. The lock-based access restriction inhibits a register update until the next system reset or requires a special key to unlock access.

References:

- Functional description: in this Reference Manual, see notes about register protection features for a specific register or a group of registers in the register-description sections for SIM, SCG, ERM, RCM, MSCM, and others
- Register protection in safety concept: see Safety Manual

### 6.2.7 CRC

The CRC unit supports the detection of accidental alteration of data in memory or configuration registers by calculating its CRC signature and comparing it to a previously calculated CRC. The CRC module can also detect erroneous corruption of data during transmission or storage.

References:

- Functional description: in this Reference Manual, see [CRC](#)
- CRC in safety concept: see Safety Manual chapter

### 6.2.8 Diversity of system resources

Features that are relevant to functional safety usually have redundant support in the system. S32K1xx offers a diversity of system resources to provide this support.

- Digital inputs can be replicated to acquire safety-critical inputs redundantly
- Safety-critical digital outputs can always be written redundantly or in combination with a read-back operation
- Analog inputs can operate in oversampling mode to detect transient faults affecting the ADC channel, and two ADC units can acquire and digitize redundant copies of an analog signal connected to a safety-relevant signal
- For cases of communication-channel redundancy for safety reasons, S32K1xx offers redundant instances of communication peripherals:
  - Synchronous Serial Communication Controller (LPSPI) modules

- FlexIO module: capable of supporting a wide range of protocols (UART, I2C, SPI, I2S) and PWM/waveform generation
- UART modules: support UART and LIN communication

### References:

- Functional description: in this Reference Manual, see [SIM](#), [LPSPI](#), [LPI2C](#), [FlexIO](#), and [LPUART](#)
- Diversity of system resources in safety concept: see Safety Manual

# Chapter 7

## CM4 Overview

### 7.1 Arm Cortex-M4F core configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by Arm and can be found at [arm.com](http://arm.com).

**Figure 7-1. Core configuration**

**Table 7-1. Reference links to related information**

| Topic                              | Related module                                                               | Reference                                                  |

## 7.1.1 Buses, interconnects, and interfaces

The Arm Cortex-M4 core has four buses as described in the following table.

**Table 7-2. Arm core buses**

| Bus name                     | Description                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instruction code (ICODE) bus | The ICODE and DCODE buses are muxed. This muxed bus is called the CODE bus and is connected to the crossbar switch via a single master port.                                                               |
| Data code (DCODE) bus        |                                                                                                                                                                                                            |
| System bus                   | The system bus is connected to a separate master port on the crossbar.                                                                                                                                     |
| Private peripheral (PPB) bus | The PPB provides access to these modules: <ul style="list-style-type: none"> <li>• Arm modules such as the NVIC, ITM, DWT, FBP, and ROM table</li> <li>• NXP Miscellaneous Control Module (MCM)</li> </ul> |

## 7.1.2 System Tick Timer

The System Tick Timer's clock source is always the core clock, CORE\_CLK. This results in the following:

- The CLKSOURCE bit in SysTick Control and Status register is always set to select the core clock.
- Because the timing reference (CORE\_CLK) is a variable frequency, the TENMS bit in the SysTick Calibration Value Register is always zero.
- The NOREF bit in SysTick Calibration Value Register is always set, implying that CORE\_CLK is the only available source of reference timing.

### 7.1.3 Debug facilities

This chip has extensive debug capabilities including run control and tracing capabilities. This is a standard Arm debug port that supports JTAG and SWD interfaces.

### 7.1.4 Caches

This device includes one 4 KB code cache to minimize the performance impact of memory access latencies. The code cache exists on the I/D bus, and there is no cache on the system bus.

Features of the cache are:

- 2-way set associative
- 4 word lines
- Lines can be individually flushed
- Entire cache can be flushed at once

#### 7.1.4.1 Control

For control purposes, the cache can be in one of these states:

1. Write Back / Write Allocate (WBWA)
2. Write Through
3. No cache

For each defined region there will be 2 bits allocated on the control register (see [PCCRRMR](#) that determines the cache state for the memory region associated with this section. The user can only "lower" the cache attribute, given the fixed relationship of WBWA > WT > NC - so, you can demote a WBWA region to either WT or NC, you can demote a WT space to NC. In order to change the state upwards a system reset is required.

#### NOTE

See [LMEM](#) for the cache reset states.

### 7.1.5 Core privilege levels

The Arm documentation uses different terms than this document to distinguish between privilege levels.

Table 7-3. Terms used

| If you see this term... | it also means this term... |
|-------------------------|----------------------------|
| Privileged              | Supervisor                 |
| Unprivileged or user    | User                       |

7.2 Nested Vectored Interrupt Controller (NVIC) Configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by Arm and can be found at [arm.com](http://arm.com).

Figure 7-2. NVIC configuration

Table 7-4. Reference links to related information

| Topic                        | Related module                              | Reference                                                                                        |
|------------------------------|---------------------------------------------|--------------------------------------------------------------------------------------------------|
| Full description             | Nested Vectored Interrupt Controller (NVIC) | <a href="#">Arm Cortex-M4F Technical Reference Manual - Nested Vectored Interrupt Controller</a> |
| System memory map            | —                                           | Refer to the S32K1xx_memory_map.xlsx attached to this document.                                  |
| Clocking                     | —                                           | <a href="#">Clock distribution</a>                                                               |
| Power management             | —                                           | <a href="#">Power management</a>                                                                 |
| Private Peripheral Bus (PPB) | Arm Cortex-M4 core                          | <a href="#">Arm Cortex-M4F Technical Reference Manual - Private Peripheral Bus (PPB)</a>         |

7.2.1 Interrupt priority levels

This device supports 16 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 4 bits. For example, the IPR0 diagram is shown below.

## 7.2.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external  $\overline{\text{NMI}}$  signal. The pin on which the  $\overline{\text{NMI}}$  signal is multiplexed must be configured for the  $\overline{\text{NMI}}$  function in order to generate the non-maskable interrupt request.

See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for details on NMI pad.

## 7.2.3 Determining the bitfield and register location for configuring a particular interrupt

Suppose you need to configure the low-power timer (LPTMR) interrupt. The following table is an excerpt of the LPTMR row from the file 'S32K1xx\_DMA\_INT\_mapping.xlsm' attached to this Reference Manual.

**Table 7-6. LPTMR interrupt vector assignment**

| Address     | Vector | IRQ <sup>1</sup> | NVIC non-IPR register number <sup>2</sup> | NVIC IPR register number <sup>3</sup> | Source module   |
|-------------|--------|------------------|-------------------------------------------|---------------------------------------|-----------------|
| 0x0000_0128 | 74     | 58               | 1                                         | 14                                    | Low Power Timer |

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is:  $\text{IRQ} \div 32$
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is:  $\text{IRQ} \div 4$

The NVIC registers you would use to configure the interrupt are:

- NVICISER1
- NVICICER1
- NVICISPR1
- NVICICPR1
- NVICIABR1
- NVICIPR14

To determine the particular IRQ's bitfield location within these particular registers:

- NVICISER1, NVICICER1, NVICISPR1, NVICICPR1, NVICIABR1 bit location =  $\text{IRQ} \bmod 32 = 26$
- NVICIPR14 bitfield starting location =  $8 \times (\text{IRQ} \bmod 4) + 4 = 20$

Since the NVICIPR bitfields are 4-bit wide (16 priority levels), the NVICIPR14 bitfield range is 20-23

Therefore, the following bitfield locations are used to configure the LPTMR interrupts:

- NVICISER1[26]
- NVICICER1[26]
- NVICISPR1[26]
- NVICICPR1[26]
- NVICIABR1[26]
- NVICIPR14[23:20]

### 7.3 Asynchronous Wake-up Interrupt Controller (AWIC) Configuration

# Chapter 8

## CM0+ Overview

### 8.1 Arm Cortex-M0+ core introduction

The enhanced Arm Cortex M0+ is the member of the Cortex-M Series of processors targeting microcontroller cores focused on very cost sensitive, low power applications. It has a single 32-bit AMBA AHB-Lite interface and includes an NVIC component. It also has hardware debug functionality including support for simple program trace capability. The processor supports the Armv6-M instruction set (Thumb) architecture including all but three 16-bit Thumb opcodes (52 total) plus seven 32-bit instructions. It is upward compatible with other Cortex-M profile processors.

**Table 8-1. Reference links to related information**

| Topic                              | Related module                                                                      | Reference                                                  |

| Power management                   | —                                                                                   | <a href="#">Power management</a>                           |
| System/instruction/data bus module | Crossbar switch                                                                     | <a href="#">Crossbar switch</a>                            |
| Debug                              | IEEE 1149.1 JTAG<br>Serial Wire Debug (SWD)<br>MTB<br>Arm Real-Time Trace Interface | <a href="#">Debug</a>                                      |
| Interrupts                         | Nested Vectored Interrupt Controller (NVIC)                                         | <a href="#">NVIC</a>                                       |

## 8.1.1 Buses, interconnects, and interfaces

The Arm Cortex-M0+ core has two bus interfaces:

- Single 32-bit AMBA-3 AHB-Lite system interface that provides connections to peripherals and all system memory, which includes flash memory and RAM
- Single 32-bit I/O port bus interfacing to the GPIO with 1-cycle loads and stores

## 8.1.2 System tick timer

The CLKSOURCE field in SysTick Control and Status register selects either the core clock (when CLKSOURCE = 1) or a divide-by-16 of the core clock (when CLKSOURCE = 0). Because the timing reference is a variable frequency, the TENMS field in the SysTick Calibration Value Register is always 0.

## 8.1.3 Debug facilities

This device supports standard Arm 2-pin SWD debug port.

## 8.1.4 Core privilege levels

The core on this device is implemented with both privileged and unprivileged levels. The Arm documentation uses different terms than this document to distinguish between privilege levels.

| If you see this term... | it also means this term... |
|-------------------------|----------------------------|
| Privileged              | Supervisor                 |
| Unprivileged or user    | User                       |

## 8.2 Nested vectored interrupt controller (NVIC)

### 8.2.1 Interrupt priority levels

This device supports four priority levels for interrupts. Therefore, in the NVIC, each source in the IPR registers contains two bits. For example, IPR0 is shown below:

|   |             |    |    |    |    |    |             |    |    |    |    |    |             |    |    |    |    |    |             |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---|-------------|----|----|----|----|----|-------------|----|----|----|----|----|-------------|----|----|----|----|----|-------------|----|----|----|---|---|---|---|---|---|---|---|---|---|
|   | 31          | 30 | 29 | 28 | 27 | 26 | 25          | 24 | 23 | 22 | 21 | 20 | 19          | 18 | 17 | 16 | 15 | 14 | 13          | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R | IRQ3        |    |    |    |    |    | IRQ2        |    |    |    |    |    | IRQ1        |    |    |    |    |    | IRQ0        |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W | 0 0 0 0 0 0 |    |    |    |    |    | 0 0 0 0 0 0 |    |    |    |    |    | 0 0 0 0 0 0 |    |    |    |    |    | 0 0 0 0 0 0 |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 8.2.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external  $\overline{\text{NMI}}$  signal. The pin the  $\overline{\text{NMI}}$  signal is multiplexed on, must be configured for the  $\overline{\text{NMI}}$  function to generate the non-maskable interrupt request. See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for details on NMI pad.

### 8.2.3 Determining the bitfield and register location for configuring a particular interrupt

Suppose you need to configure the SPI0 interrupt. The following table is an excerpt of the FlexCAN row from the file 'S32K1xx\_DMA\_INT\_mapping.xlsm' attached to this Reference Manual.

**Table 8-3. Interrupt vector assignments**

| Address     | Vector | IRQ <sup>1</sup> | NVIC IPR register number <sup>2</sup> | Source module |
|-------------|--------|------------------|---------------------------------------|---------------|
| 0x0000_006C | 27     | 11               | 2                                     | FlexCAN       |

1. Indicates the NVIC's interrupt source number.

2. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is:  $\text{IRQ} \div 4$ .

- The NVIC registers you would use to configure the interrupt are:
  - NVICIPR2
- To determine the particular IRQ's field location within these particular registers:
  - NVICIPR2 field starting location =  $8 * (\text{IRQ} \bmod 4) + 6 = 22$

Since the NVICIPR fields are 2-bit wide (4 priority levels), the NVICIPR2 field range is 22–23.

Therefore, the following field locations are used to configure the FlexCAN interrupts:

- NVICIPR2[23:22]

## 8.3 AWIC introduction

The primary function of the AWIC block is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.

**Table 8-4. Reference links to related information**

| Topic                                       | Related module | Reference                                                                      |
|---------------------------------------------|----------------|--------------------------------------------------------------------------------|
| System memory map                           | —              | Refer to the S32K1xx_memory_map.xlsx attached to Reference Manual for details. |
| Clocking                                    | —              | <a href="#">Clock distribution</a>                                             |
| Power management                            | —              | <a href="#">Power management</a>                                               |
| Nested Vectored Interrupt Controller (NVIC) | —              | <a href="#">NVIC</a>                                                           |
| Wake-up requests                            | —              | <a href="#">AWIC wake-up sources</a>                                           |

### 8.3.1 Wake-up sources

The device uses the following internal and external inputs to the AWIC module.

**Table 8-5. AWIC stop and VLPS wake-up sources**

| Wake-up source          | Description                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Available system resets | RESET pin, WDOG, JTAG                                                                                                            |
| Pin interrupts          | Port Control Module - Any enabled pin interrupt is capable of waking the system                                                  |

# Chapter 9

## Micro Trace Buffer (MTB)

### 9.1 Introduction

Microcontrollers using the Cortex-M0+ processor core include support for a CoreSight Micro Trace Buffer to provide program trace capabilities.

The proper name for this function is the CoreSight Micro Trace Buffer for the Cortex-M0+ Processor; in this document, it is simply abbreviated as the MTB.

The simple program trace function creates instruction address change-of-flow data packets in a user-defined region of the system RAM. Accordingly, the system RAM controller manages requests from two sources:

- AMBA-AHB reads and writes from the system bus
- program trace packet writes from the processor

As part of the MTB functionality, there is a MTB\_DWT (Data Watchpoint and Trace) module that allows the user to define watchpoint addresses, or optionally, an address and data value, that when triggered, can be used to start or stop the program trace recording.

#### 9.1.1 Overview

As shown in the main block diagram, the platform RAM (PRAM) controller connects to two input buses:

- the crossbar slave port for system bus accesses
- a "private execution MTB port" from the core

The logical paths from the crossbar master input ports to the PRAM controller are highlighted along with the private execution trace port from the processor core. The private MTB port signals the instruction address information needed for the 64-bit program trace packets written into the system RAM. The PRAM controller output interfaces to the attached RAM array. In this document, the PRAM controller is the MTB\_RAM controller.

The following information is taken from the ARM CoreSight Micro Trace Buffer documentation.

"The execution trace packet consists of a pair of 32-bit words that the MTB generates when it detects the processor PC value changes non-sequentially. A non-sequential PC change can occur during branch instructions or during exception entry.

The processor can cause a trace packet to be generated for any instruction.

The following figure shows how the execution trace information is stored in memory as a sequence of packets.

**Figure 9-1. MTB execution trace storage format**

The first, lower addressed, word contains the source of the branch, the address it branched from. The value stored only records bits[31:1] of the source address, because Thumb instructions are at least halfword aligned. The least significant bit of the value is the A-bit. The A-bit indicates the atomic state of the processor at the time of the branch, and can differentiate whether the branch originated from an instruction in a program, an exception, or a PC update in Debug state. When it is zero the branch originated from an instruction, when it is one the branch originated from an exception or PC update in Debug state. This word is always stored at an even word location.

The second, higher addressed word contains the destination of the branch, the address it branched to. The value stored only records bits[31:1] of the branch address. The least significant bit of the value is the S-bit. The S-bit indicates where the trace started. An S-bit value of 1 indicates where the first packet after the trace started and a value of 0 is used for other packets. Because it is possible to start and stop tracing multiple times in a trace session, the memory might contain several packets with the S-bit set to 1. This word is always stored in the next higher word in memory, an odd word address.

When the A-bit is set to 1, the source address field contains the architecturally-preferred return address for the exception. For example, if an exception was caused by an SVC instruction, then the source address field contains the address of the following instruction. This is different from the case where the A-bit is set to 0. In this case, the source address contains the address of the branch instruction.

For an exception return operation, two packets are generated:

- The first packet has the:
  - Source address field set to the address of the instruction that causes the exception return, BX or POP.
  - Destination address field set to bits[31:1] of the EXC\_RETURN value. See the ARM v6-M Architecture Reference Manual.
  - The A-bit set to 0.
- The second packet has the:
  - Source address field set to bits[31:1] of the EXC\_RETURN value.
  - Destination address field set to the address of the instruction where execution commences.
  - A-bit set to 1."

Given the recorded change-of-flow trace packets in system RAM and the memory image of the application, a debugger can read out the data and create an instruction-by-instruction program trace. In keeping with the low area and power implementation cost design targets, the MTB trace format is less efficient than other CoreSight trace modules, for example, the ETM (Embedded Trace Macrocell). Since each branch packet is 8 bytes in size, a 1 KB block of system RAM can contain 128 branches. Using the Dhrystone 2.1 benchmark's dynamic runtime as an example, this corresponds to about 875 instructions per KB of trace RAM, or with a zero wait state memory, this corresponds to approximately 1600 processor cycles per KB. This metric is obviously very sensitive to the runtime characteristics of the user code.

The MTB\_DWT function (not shown in the core platform block diagram) monitors the processor address and data buses so that configurable watchpoints can be detected to trigger the appropriate response in the MTB recording.

## 9.1.2 Features

The key features of the MTB\_RAM and MTB\_DWT include:

- Memory controller for system RAM and Micro Trace Buffer for program trace packets
- Read/write capabilities for system RAM accesses, write-only for program trace packets

- Supports zero wait state response to system bus accesses when no trace data is being written
- Can buffer two AHB address phases and one data write for system RAM accesses
- Supports 64-bit program trace packets including source and destination instruction addresses
- Program trace information in RAM available to MCU's application code or external debugger
- Program trace watchpoint configuration accessible by MCU's application code or debugger
- Location and size of RAM trace buffer is configured by software
- Two DWT comparators (addresses or address + data) provide programmable start/stop recording
- CoreSight compliant debug functionality

### 9.1.3 Modes of operation

The MTB\_RAM and MTB\_DWT functions do not support any special modes of operation. The MTB\_RAM controller, as a memory-mapped device located on the platform's slave AHB system bus, responds strictly on the basis of memory addresses for accesses to its attached RAM array. The MTB private execution bus provides program trace packet write information to the RAM controller. Both the MTB\_RAM and MTB\_DWT modules are memory-mapped, so their programming models can be accessed.

All functionality associated with the MTB\_RAM and MTB\_DWT modules resides in the core platform's clock domain; this includes its connections with the RAM array.

## 9.2 Memory map and register definition

The MTB\_RAM and MTB\_DWT modules each support a sparsely-populated 4 KB address space for their programming models. For each address space, there are a variety of control and configurable registers near the base address, followed by a large unused address space and finally a set of CoreSight registers to support dynamic determination of the debug configuration for the device.

Accesses to the programming model follow standard ARM conventions. Taken from the ARM CoreSight Micro Trace Buffer documentation, these are:

- Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in UNPREDICTABLE behavior.

- The behavior of the MTB is UNPREDICTABLE if the registers with UNKNOWN reset values are not programmed prior to enabling trace.
- Unless otherwise stated in the accompanying text:
  - Do not modify reserved register bits
  - Ignore reserved register bits on reads
  - All register bits are reset to a logic 0 by a system or power-on reset
  - Use only word size, 32-bit, transactions to access all registers
  - DWT registers are not accessible by the processor. Access by DAP interface is allowed.

## 9.2.1 MTB\_DWT Memory Map

The MTB\_DWT programming model supports a very simplified subset of the v7M debug architecture and follows the standard ARM DWT definition.

**MTB\_DWT memory map**

| Address offset (hex) | Register name                                          | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|--------------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | MTB DWT Control Register (MTB_DWT_CTRL)                | 32              | R      | 2F00_0000h  | <a href="#">9.2.1.1/132</a> |

**MTB\_DWT\_COMPn field descriptions**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMP  | Reference value for comparison<br><br>If MTBDWT_COMP0 is used for a data value comparator and the access size is byte or halfword, the data value must be replicated across all appropriate byte lanes of this register. For example, if the data is a byte-sized "x" value, then COMP[31:24] = COMP[23:16] = COMP[15:8] = COMP[7:0] = "x". Likewise, if the data is a halfword-size "y" value, then COMP[31:16] = COMP[15:0] = "y". |

**9.2.1.3 MTB\_DWT Comparator Mask Register (MTB\_DWT\_MASKn)**

The MTBDWT\_MASKn registers define the size of the ignore mask applied to the reference address for address range matching by comparator n. Note the format of this mask field is different than the MTB\_MASTER[MASK].

Address: 0h base + 24h offset + (16d × i), where i=0d to 1d

| 31–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| MASK             | <p>MASK</p> <p>The value of the ignore mask, 0-31 bits, is applied to address range matching. MASK = 0 is used to include all bits of the address in the comparison, except if MASK = 0 and the comparator is configured to watch instruction fetch addresses, address bit [0] is ignored by the hardware since all fetches must be at least halfword aligned. For MASK != 0 and regardless of watch type, address bits [x-1:0] are ignored in the address comparison.</p> <p>Using a mask means the comparator matches on a range of addresses, defined by the unmasked most significant bits of the address, bits [31:x]. The maximum MASK value is 24, producing a 16 Mbyte mask. An attempted write of a MASK value &gt; 24 is limited by the MTBDWT hardware to 24.</p> <p>If MTBDWT_COMP0 is used as a data value comparator, then MTBDWT_MASK0 should be programmed to zero.</p> |

### 9.2.1.4 MTB\_DWT Comparator Function Register 0 (MTB\_DWT\_FCT0)

The MTBDWT\_FCTn registers control the operation of comparator n.

Address: 0h base + 28h offset = 28h

### 9.2.1.5 MTB\_DWT Comparator Function Register 1 (MTB\_DWT\_FCT1)

The MTBDWT\_FCTn registers control the operation of comparator n. Since the MTB\_DWT only supports data value comparisons on comparator 0, there are several fields in the MTBDWT\_FCT1 register that are RAZ/WI (bits 12, 11:10, 8).

Address: 0h base + 38h offset = 38h

### 9.2.1.6 MTB\_DWT Trace Buffer Control Register (MTB\_DWT\_TBCTRL)

The MTBDWT\_TBCTRL register defines how the watchpoint comparisons control the actual trace buffer operation.

Recall the MTB supports starting and stopping the program trace based on the watchpoint comparisons signaled via TSTART and TSTOP. The watchpoint comparison signals are enabled in the MTB's control logic by setting the appropriate enable bits, MTB\_MASTER[TSTARTEN, TSTOPEN]. In the event of simultaneous assertion of both TSTART and TSTOP, TSTART takes priority. There are two signals formed by the MTB\_DWT module and driven to the MTB\_RAM controller: TSTART (trace start) and TSTOP (trace stop). These signals can be configured using the trace watchpoints to define programmable addresses and data values to affect the program trace recording state.

Address: 0h base + 200h offset = 200h

### 9.2.1.7 Device Configuration Register (MTB\_DWT\_DEVICECFG)

This register indicates the device configuration. It is hardwired to specific values used during the auto-discovery process by an external debug agent.

Address: 0h base + FC8h offset = FC8h

**MTB\_DWT\_DEVICECFG field descriptions**

| Field     | Description                            |
|-----------|----------------------------------------|
| DEVICECFG | DEVICECFG<br>Hardwired to 0x0000_0000. |

### 9.2.1.8 Device Type Identifier Register (MTB\_DWT\_DEVICETYPID)

This register indicates the device type ID. It is hardwired to specific values used during the auto-discovery process by an external debug agent.

Address: 0h base + FCCh offset = FCCh

**MTB\_DWT\_DEVICETYPID field descriptions**

| Field       | Description                              |
|-------------|------------------------------------------|
| DEVICETYPID | DEVICETYPID<br>Hardwired to 0x0000_0004. |

### 9.2.1.9 Peripheral ID Register (MTB\_DWT\_PERIPHID<sub>n</sub>)

These registers indicate the peripheral IDs. They are hardwired to specific values used during the auto-discovery process by an external debug agent. See bit field descriptions for the reset values.

Address: 0h base + FD0h offset + (4d × i), where i=0d to 7d

| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0 |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|
| R     | PERIPHID |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
| W     |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
| Reset | x*       | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* |   |

\* Notes:

- x = Undefined at reset.

#### MTB\_DWT\_PERIPHID<sub>n</sub> field descriptions

| Field    | Description                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------|
| PERIPHID | PERIPHID<br>Peripheral ID1 is hardwired to 0x0000_00E0; ID2 to 0x0000_0008; and all the others to 0x0000_0000. |

### 9.2.1.10 Component ID Register (MTB\_DWT\_COMPID<sub>n</sub>)

These registers indicate the component IDs. They are hardwired to specific values used during the auto-discovery process by an external debug agent. See bit field descriptions for the reset values.

Address: 0h base + FF0h offset + (4d × i), where i=0d to 3d

| Bit   | 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0 |
|-------|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|

## Chapter 10

# Miscellaneous Control Module (MCM)

### 10.1 Chip-specific MCM information

The following table summarizes the chip-specific register reset values of this module for each chip in the product series.

**Table 10-1. MCM register reset values**

| Register  | S32K116   | S32K118   | S32K142   | S32K144   | S32K14xW  | S32K146   | S32K148   |
|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| MCM_LMDR0 | 8104_0000 | 8104_0000 | 8504_0003 | 8604_0003 | 8604_0003 | 8704_0003 | 8804_0003 |
| MCM_LMDR1 | 8504_2003 | 9604_2003 | 8504_2003 | 8604_2003 | 8604_2003 | 8704_2003 | 8804_2003 |
| MCM_LMDR2 | NA        | NA        | 8424_40A0 | 8424_40A0 | 8424_40A0 | 8424_40A0 | 8424_40A0 |
| MCM_PLASC | 0007      | 0007      | 0007      | 0007      | 0007      | 0007      | 000F      |
| MCM_PLAMC | 0005      | 0005      | 0007      | 0007      | 0007      | 0007      | 000F      |

#### NOTE

- For S32K11x , LMDR information can be inferred for SRAM size as below:
  - S32K116: LMDR1[LMSZH]=0, LMDR1[LMSZH]=0x5 , so SRAM\_U size  $1 \times (16)$  KB = 16 KB. Actual size is 16 KB – 2 KB = 14 KB
  - S32K118: LMDR1[LMSZH]=1, LMDR1[LMSZH]=0x6 , so SRAM\_U size  $0.75 \times (32)$  KB = 24 KB. Actual size is 24 KB – 2 KB = 22 KB
- For S32K14x and S32K14xW variants SRAM is the tightly coupled SRAM (TCM), while for S32K11x variants SRAM is at the crossbar slave side.

Address offset of LMPEIR register varies between S32K14x, S32K14xW, and S32K11x as given below.

**Table 10-2. MCM register offset**

| Register   | S32K14x offset | S32K14xW offset | S32K11x offset |
|------------|----------------|-----------------|----------------|
| MCM_LMPEIR | 0x488          | 0x488           | 0x484          |

## 10.2 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions.

### NOTE

- Cache write buffer is not supported on S32K1xx and S32K14xW variants.
- ECC on SRAML/MTB, FPU, and Cache is not supported on S32K11x.

### 10.2.1 Features

The MCM includes the following feature:

- Program-visible information on the platform configuration and revision

## 10.3 Memory map/register descriptions

The memory map and register descriptions below describe the Miscellaneous Control Module registers.

### NOTE

- All registers are accessible only in Supervisor mode. User mode accesses will generate an error.
- Writing to read-only MCM\_PLASC and MCM\_PLAMC registers, would generate a bus error.

## MCM memory map

| Address offset (hex) | Register name                                           | Width (in bits) | Access | Reset value                 | Section/ page               |
|----------------------|---------------------------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| 8                    | Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)  | 16              | R      | 0007h                       | <a href="#">10.3.1/145</a>  |
| A                    | Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC) | 16              | R      | 0007h                       | <a href="#">10.3.2/146</a>  |

| 4A4                  | LMEM Fault Data Low Register (MCM_LMFDLR)               | 32              | R      | 0000_0000h                  | <a href="#">10.3.14/166</a> |

## 10.3.1 Crossbar Switch (AXBS) Slave Configuration (MCM\_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: 0h base + 8h offset = 8h

**10.3.4 Interrupt Status and Control Register (MCM\_ISCR)**

ISCR defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status fields associated with the core's floating-point exceptions and the bus errors associated with the core's cache write buffer. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR. Attempted writes to these fields are ignored. After the flags are set, they remain asserted until software clears the corresponding FPSCR field.

**NOTE**

This register is Reserved for S32K11x variants.

Address: 0h base + 10h offset = 10h

**10.3.5 Process ID Register (MCM\_PID)**

This register drives the M0\_PID and M1\_PID values in the Memory Protection Unit (MPU). System software loads this register before passing control to a given user mode process. If the PID of the process does not match the value in this register, a bus error occurs. See the MPU chapter for more details.

*Table continues on the next page...*

**MCM\_CPO field descriptions (continued)**

| Field | Description                |
|-------|----------------------------|
| 0     | Request is cleared.        |
| 1     | Request Compute Operation. |

**10.3.7 Local Memory Descriptor Register (MCM\_LMDR<sub>n</sub>)**

The LMDR<sub>n</sub> registers mapping to the LMEMs is as follows:

- LMDR0: SRAM\_L
- LMDR1: SRAM\_U

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information on the attached memories as well as configurable controls (where appropriate).

Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information. Reads from any other bus master return all zeroes. Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields. Privileged writes from other bus masters are ignored. Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

## Memory map/register descriptions

Address: 0h base + 400h offset + (4d × i), where i=0d to 1d

**10.3.8 Local Memory Descriptor Register2 (MCM\_LMDR2)**

The LMDR2 registers mapping to the LMEMs representing PC CACHE.

**NOTE**

This value represents the maximum available cache within the entire family. See [Figure 2-3](#) to view the specific amount of cache for a particular device.

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information on the attached memories as well as configurable controls (where appropriate).

Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information. Reads from any other bus master return all zeroes. Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields. Privileged writes from other bus masters are ignored. Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

Address: 0h base + 408h offset = 408h

**10.3.10 LMEM Parity and ECC Interrupt Register (MCM\_LMPEIR)****NOTE**

Writes of 1 to the error bit in LMPEIR[23:0] can clear the interrupt flag. For S32K11x variants, MCM interrupt for ECC is not supported and this register only captures the event.

## 10.4 Functional description

This section describes the functional description of MCM module.

### 10.4.1 Interrupts

The MCM interrupt is generated if any of the following is true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FIOCE) and an invalid occurs (FIOC)
- SRAM\_L correctable (1-bit) ECC error
- SRAM\_L uncorrectable ECC error
- SRAM\_U correctable (1-bit) ECC error
- SRAM\_U uncorrectable ECC error
- PC data parity error
- PC tag parity error
- Cache write buffer error

#### NOTE

The above interrupt is not applicable for S32K11x variants.

#### 10.4.1.1 Determining source of the interrupt

These steps can be used to determine the exact source of the interrupt:

1. Logical AND the interrupt status flags with the corresponding interrupt enable bits: ISCR[31:16] and ISCR[15:0].
2. Search the result for asserted bits which indicate the exact interrupt sources.

### **NOTE**

ECC and Parity interrupts are determined by LMPECR (interrupt enable) and LMPEIR (interrupt source).

# Chapter 11

## System Integration Module (SIM)

### 11.1 Chip-specific SIM information

Some aspects of the SIM vary across the products in the series. See following sections for details.

#### 11.1.1 SIM register/bitfield implementation

Not all register bitfields shown in the SIM memory map are implemented in every S32K1xx and S32K14xW variants. Register/ register bit field availability vary accordingly to the availability of a module/the number of module instances present in a variant. See [Figure 2-3](#) for details on module and instance information. The notes below describes the availability. See following sections for details.

#### NOTE

- CHIPCTL[PDB\_BB\_SEL\_1] and CHIPCTL[PDB\_BB\_SEL\_2] bit fields at position 22 and 23 respectively are for PDB back to back select. These bit fields are available in S32K14xW variants only.
- MISCTRL0[ECC\_EEERAM\_STAT] and MISCTRL0[ECC\_MGRAM\_STAT] bit fields at position 11 and 12 respectively are for ECC double bit fault. These bit fields are available in S32K14xW variants only.
- PLATCGC[CGCGPIO] bit field at position 5 for GPIO Clock Gating Control. This bit is available in S32K11x variants only.
- The read of the SIM registers is affected during EEERAM commands. For more information see note 'During execution of the SetRAM 0xFF' in [Chip-specific FTFC information](#).

11.1.1.1 Chip Control register (CHIPCTL)

11.1.1.1.1 Offset

| Register | Offset |
|----------|--------|
| CHIPCTL  | 4h     |

11.1.1.1.2 Function

SIM\_CHIPCTL contains the controls for selecting ADC COCO trigger, trace clock, clock out source, PDB back-to-back mode, and ADC interleave channel.

NOTE

Bits 31:16 are reset on POR.

11.1.1.1.3 Diagram

### 11.1.1.1.4 Fields

## 11.2 Introduction

The System Integration Module (SIM) provides system control and chip configuration registers.

### 11.2.1 Features

Features of the SIM include:

- System clocking configuration
- Flash memory and system RAM size configuration
- FlexTimer clock channel and configuration
- ADC trigger selection
- LPO clock source selection
- ENET clock control
- Flash memory configuration
- System device identification (ID)

## 11.3 Memory map and register definition

The SIM contains many fields for selecting the clock source and dividers for various module clocks. See section: Clock Distribution chapter for more information, including block diagrams and clock definitions.

**NOTE**

The SIM registers can only be written in supervisor mode. In user mode, write accesses are blocked and will result in a bus error.

**NOTE**

Writing to Read-Only registers may /may not generate Transfer error.

## 11.3.1 SIM register descriptions

### 11.3.1.1 SIM memory map

SIM base address: 4004\_8000h

### 11.3.1.2 Chip Control register (CHIPCTL)

### 11.3.1.2.1 Offset

| Register | Offset |
|----------|--------|
| CHIPCTL  | 4h     |

### 11.3.1.2.2 Function

SIM\_CHIPCTL contains the controls for selecting ADC COCO trigger, trace clock, clock out source, PDB back-to-back mode, and ADC interleave channel.

#### NOTE

Bits 31:16 are reset on POR.

### 11.3.1.2.3 Diagram

## 11.3.1.8 System Device Identification Register (SDID)

### 11.3.1.8.1 Offset

| Register | Offset |
|----------|--------|
| SDID     | 24h    |

### 11.3.1.8.2 Function

#### NOTE

This register's reset value is loaded during system reset from flash memory IFR.

### 11.3.1.8.3 Diagram

### 11.3.1.8.4 Fields

| Field               | Function                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-28<br>GENERATION | S32K product series generation<br>Specifies the generation of the S32K product series of chips. Generation for this chip is 1.                                                                                                                                                                                                                                                                        |
| 27-24<br>SUBSERIES  | Subseries<br>Specifies the sub-series of the chip. The value is 4 (S32K14x and S32K14xW chip) or 1 (S32K11x chip).                                                                                                                                                                                                                                                                                    |
| 23-20<br>DERIVATE   | Derivate<br>Specifies the derivate of the chip. The value is 8 (S32K148), 6 (S32K146), 4 (S32K144), 5 (S32K144W), 2 (S32K142), 3 (S32K142W) 8 (S32118), or 6 (S32K116).                                                                                                                                                                                                                               |
| 19-16<br>RAMSIZE    | RAM size<br>This field specifies the total amount of system RAM available on the chip, including FlexRAM.                                                                                                                                                                                                                                                                                             |
| 15-12<br>REVID      | Device revision number<br>Specifies the silicon implementation number for the chip. The value is 0 (for S32K148, S32K146, S32K142, S32K118, and S32K116) and 1 (for S32K144).                                                                                                                                                                                                                         |

### 11.3.1.10 Flash Configuration Register 1 (FCFG1)

#### 11.3.1.10.1 Offset

| Register | Offset |
|----------|--------|
| FCFG1    | 4Ch    |

#### 11.3.1.10.2 Function

#### NOTE

The reset value of DEPART field of this register is loaded during system reset from flash memory IFR.

**NOTE**

Attempted writes to this register may result in unpredictable behavior.

### 11.3.1.11 Unique Identification Register High (UIDH)

#### 11.3.1.11.1 Offset

| Register | Offset |
|----------|--------|
| UIDH     | 54h    |

#### 11.3.1.11.2 Function

#### NOTE

- UID127\_96, UID95\_64, UID63\_32, and UID31\_0 together represents 128-bit unique identification number for this device.
- This register's reset value is loaded during system reset from flash memory IFR.

#### 11.3.1.11.3 Diagram

### 11.3.1.11.4 Fields

| Field     | Function                            |
|-----------|-------------------------------------|
| 31-0      | Unique Identification               |
| UID127_96 | Unique identification for the chip. |

### 11.3.1.12 Unique Identification Register Mid-High (UIDMH)

#### 11.3.1.12.1 Offset

| Register | Offset |
|----------|--------|
| UIDMH    | 58h    |

#### 11.3.1.12.2 Function

#### NOTE

This register's reset value is loaded during system reset from flash memory IFR.

#### 11.3.1.12.3 Diagram

#### 11.3.1.12.4 Fields

| Field    | Function                            |
|----------|-------------------------------------|
| 31-0     | Unique Identification               |
| UID95_64 | Unique identification for the chip. |

### 11.3.1.13 Unique Identification Register Mid Low (UIDML)

#### 11.3.1.13.1 Offset

| Register | Offset |
|----------|--------|
| UIDML    | 5Ch    |

#### 11.3.1.13.2 Function

##### NOTE

This register's reset value is loaded during system reset from flash memory IFR.

#### 11.3.1.13.3 Diagram

#### 11.3.1.13.4 Fields

| Field    | Function                            |
|----------|-------------------------------------|
| 31-0     | Unique Identification               |
| UID63_32 | Unique identification for the chip. |

### 11.3.1.14 Unique Identification Register Low (UIDL)

### 11.3.1.14.1 Offset

| Register | Offset |
|----------|--------|
| UIDL     | 60h    |

### 11.3.1.14.2 Function

#### NOTE

This register's reset value is loaded during system reset from flash memory IFR.

### 11.3.1.14.3 Diagram

### 11.3.1.14.4 Fields

| Field   | Function                            |
|---------|-------------------------------------|
| 31-0    | Unique Identification               |
| UID31_0 | Unique identification for the chip. |

## 11.3.1.15 System Clock Divider Register 4 (CLKDIV4)

### 11.3.1.15.1 Offset

| Register | Offset |
|----------|--------|
| CLKDIV4  | 68h    |

### 11.3.1.15.2 Function

#### NOTE

This register is Reserved for S32K11x variants.

## Chapter 12

# Port Control and Interrupts (PORT)

### 12.1 Chip-specific PORT information

Not all pin control settings mentioned in PORT\_PCRn register are configurable for all pins. Refer 'Bits Configurable' field in 'IO Signal Table' tab of IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual. The bits apart from 'Bit Configurable' fields are reserved and should not be varied from the reset values.

PCR bits corresponding to reset pad are non-sticky bits and on a functional reset, reset functionality on this pin will be resumed. Prior to entering any ALT functionality, PCR of corresponding pad should be properly configured.

On this chip, the pullup and pulldown enables are controllable in analog or disabled pin muxing mode (corresponding to PORT\_PCRn[MUX]=3'b000). Before entering Analog mode (ALT0 corresponding to PORT\_PCRn[MUX]=3'b000 for corresponding pads for which Analog functionality is available), PUE and PUS should be configured as 0 in corresponding PCR register.

PORT\_PCRn[PFE] is configurable for only PTA5 and PTD3. See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual. PFE for these should be configured in ALT7 mode only. For other modes, PFE should be kept 0.

The corresponding PAD should be configured for disabled mode(ALT0) prior to configuring PORT\_DFER register.

Any pad configuration done in RUN/VLPR mode is retained in low power modes(STOP1,STOP2/VLPS).

Wait mode is not supported on this device.

See [Module operation in available power modes](#) for details on available power modes.

## 12.1.1 Number of PCRs

The number of PCRs for each PORT varies across the products in the S32K1xx and S32K14xW series. The following table shows the number of PCRs for each PORT on each product. [Memory map and register definition](#) documents the superset number of implemented ports. PCR registers corresponding to ports which are not present in a particular device are read only 0. See the RM attachments IO Signal Description Input Multiplexing sheet(s) for details on the count of PCRs on each product.

**Table 12-1. PCRs on each product**

| PORT   | Number of PCRs <sup>1</sup> |         |         |         |          |         |         |
|--------|-----------------------------|---------|---------|---------|----------|---------|---------|
|        | S32K116                     | S32K118 | S32K142 | S32K144 | S32K144W | S32K146 | S32K148 |
| PORT A | 11                          | 12      | 18      | 18      | 18       | 25      | 32      |
| PORT B | 9                           | 10      | 18      | 18      | 18       | 27      | 32      |
| PORT C | 12                          | 14      | 18      | 18      | 18       | 25      | 32      |
| PORT D | 7                           | 10      | 18      | 18      | 18       | 27      | 32      |
| PORT E | 4                           | 12      | 17      | 17      | 17       | 24      | 28      |

1. See the attachments IO Signal Description Input Multiplexing sheet(s) for details.

## 12.1.2 Finding address for PORTx\_PCRn

For example, in order to write to the PORT register of PTC3 (PTxn), the corresponding mapped register is PORTC\_PCR3 (PORTx\_PCRn):

- To find PORTC base address, look up the 'Start address' of "Port C" in "Peripheral Memory Map" tab in the attached S32K1xx\_Memory\_Map.xls. This is referred henceforth as PORTC\_Base\_address.
- To reach PCRn, refer to address 'PORTx\_Base\_address + n\*4d'. For PCR3 of PORTC, this refers to 'PORTC\_Base\_address + 3\*4d'. The attached IO Signal Description Input Muxing sheet(s) for each device provides the fields available in PCR per PORTx\_PCRn (For each PTxn pin) in the tab IO Signal Table.

## 12.1.3 I/O configuration sequence

1. Ensure pins for the peripheral are in tristate state (default out of reset).
2. Initialize peripheral clock in the Peripheral Clock Controller register(PCC) and peripheral specific clocking configurations.
3. Configure the peripheral
4. Initialize port clock for the peripheral pins in the Peripheral Clock Controller register (PCC\_PORTx).

5. Configure the peripheral pins mux and features in the Port Control and Interrupts register (PORTx\_PCRn).
6. Start communication

#### 12.1.4 Digital input filter configuration sequence

1. Configure digital pin filtering controls for the corresponding pin using PORTx\_DFCR and PORTx\_DFWR
2. Enable PORTx\_DFER[DFE]
3. Configure PORTx\_PCRn[MUX] for GPIO mode
4. Wait for delay equivalent to PORTx\_DFWR for filter enabling glitches to propagate
5. Enable the corresponding function of the pin by configuring PORTx\_PCRn[MUX]

##### 12.1.4.1 Digital input filter configuration sequence while using GPIO interrupt

1. Configure digital pin filtering controls for the corresponding pin using PORTx\_DFCR and PORTx\_DFWR
2. Enable PORTx\_DFER[DFE]
3. Configure PORTx\_PCRn[MUX] for GPIO mode
4. Wait for delay equivalent to PORTx\_DFWR for filter enabling glitches to propagate
5. Enable the interrupt on the corresponding pin by configuring PORTx\_PCRn[IRQC]

##### 12.1.4.2 Digital input filter configuration sequence while using NMI

1. Configure digital pin filtering controls for NMI pin using PORTD\_DFCR and PORTD\_DFWR
2. Enable PORTD\_DFER[3]
3. Configure PORTD\_PCR3[MUX] for GPIO mode
4. Wait for delay equivalent to PORTD\_DFWR for filter enabling glitches to propagate
5. Configure the pin for NMI mode using PORTD\_PCR3[MUX]

Before entering STOP/VLPS modes, filter clock should be configured as LPO128K\_CLK and reconfigured on wakeup, if required.

If filtering is not required in STOP/VLPS modes, filtering should be disabled using PORTx\_DFER and reconfigured on wakeup, if required. If filtering is not required in STOP/VLPS modes and is required wakeup onwards without reconfiguring PORTx\_DFER (with bus clock as filter clock), it should be ensured that:

$$\text{cycles\_tISR} \gg (\text{PORTx\_DFWR} + 3) * (\text{SCG\_xCCR}[\text{DIVBUS}] + 1)$$

where *cycles\_tISR*: Core clock cycles in Interrupt Service Routine (ISR) from system entering RUN mode till PORTx\_PCRn[ISF] clearing for corresponding pin.

(Sufficient delay should be added in ISR, if required, to achieve the above)

### 12.1.5 Reset pin configuration

The reset pin on device can be configured for alternative functionalities via PORTA\_PCR5[SSS] (see IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual). Before configuring alternative functionality for Reset Pin, set the [FOPT\[3\]](#) (RESET\_PIN\_CFG bit) to 0 in Flash memory configuration field and reflash your device. The FOPT field of flash memory configuration field will be loaded to FTFC\_FOPT read-only register at RESET. See table 'FTFC\_FOPT definition' in [FOPT boot options](#) for details.

#### NOTE

External Reset functionality will be disable after writing FOPT[3] (RESET\_PIN\_CFG bit) to 0.

## 12.2 Introduction

### 12.2.1 Overview

The Port Control and Interrupt (PORT) module provides support for port control, digital filtering, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

### 12.2.2 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin

- Asynchronous wake-up in low-power modes
- Pin interrupt is functional in all digital pin muxing modes
- Digital input filter
  - Digital input filter for each pin, usable by any digital peripheral muxed onto the pin
  - Individual enable or bypass control field per pin
  - Selectable clock source for digital input filter with a five bit resolution on filter size
  - Functional in all digital pin multiplexing modes
- Port control
  - Individual pull control fields with pullup, pulldown, and pull-disable support
  - Individual drive strength field supporting high and low drive strength
  - Individual input passive filter field supporting enable and disable of the individual input passive filter
  - Individual mux control field supporting analog or pin disabled, GPIO, and up to six chip-specific digital functions
  - Pad configuration fields are functional in all digital pin muxing modes.

## 12.2.3 Modes of operation

### 12.2.3.1 Run mode

In Run mode, the PORT operates normally.

### 12.2.3.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

### 12.2.3.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the digital input filters are bypassed unless they are configured to run from the LPO clock source.

### 12.2.3.4 Debug mode

In Debug mode, PORT operates normally.

## 12.3 External signal description

The table found here describes the PORT external signal.

**Table 12-2. Signal properties**

| Name        | Function           | I/O | Reset | Pull |
|-------------|--------------------|-----|-------|------|
| PORTx[31:0] | External interrupt | I/O | 0     | -    |

### NOTE

Not all pins within each port are implemented on each device.

## 12.4 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

**Table 12-3. PORT interface—detailed signal description**

| Signal      | I/O | Description         |                                                                                                                                                                         |
|-------------|-----|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PORTx[31:0] | I/O | External interrupt. |                                                                                                                                                                         |
|             |     | State meaning       | Asserted—pin is logic 1.<br>Negated—pin is logic 0.                                                                                                                     |
|             |     | Timing              | Assertion—may occur at any time and can assert asynchronously to the system clock.<br>Negation—may occur at any time and can assert asynchronously to the system clock. |

## 12.5 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

**PORT memory map**

| Address offset (hex) | Register name                                 | Width (in bits) | Access                | Reset value                 | Section/ page              |
|----------------------|-----------------------------------------------|-----------------|-----------------------|-----------------------------|----------------------------|
| 0                    | Pin Control Register n (PORT_PCR0)            | 32              | R/W                   | <a href="#">See section</a> | <a href="#">12.5.1/213</a> |

## 12.5.1 Pin Control Register n (PORT\_PCRn)

### NOTE

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins that are not available in a reduced-pin package offering. Unbonded pins not available in a package are disabled by default to prevent them from consuming power.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

| FILT             | Filter Length<br><br>The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled. |

**12.6 Functional description****12.6.1 Pin control**

Each port pin has a corresponding Pin Control register, PORT\_PCRn, associated with it.

The upper half of the Pin Control register configures the pin's capability to either interrupt the CPU or request a DMA transfer, on a rising/falling edge or both edges as well as a logic level occurring on the port pin. It also includes a flag to indicate that an interrupt has occurred.

The lower half of the Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup or pulldown enable
- Drive strength
- Passive input filter enable
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an I<sup>2</sup>C function is enabled on a pin, that does not override the pullup configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

The LK bit (bit 15 of Pin Control Register PCR<sub>n</sub>) allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that pin control register are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO\_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

## 12.6.2 Global pin control

The two global pin control registers allow a single register write to update the lower half of the pin control register on up to 16 pins, all with the same value. Registers that are locked cannot be written using the global pin control registers.

The global pin control registers are designed to enable software to quickly configure multiple pins within the one port for the same peripheral function. However, the interrupt functions cannot be configured using the global pin control registers.

The global pin control registers are write-only registers, that always read as 0.

### **12.6.3 Global interrupt control**

The two global interrupt control registers allow a single register write to update the upper half of the pin control register on up to 16 pins, all with the same value.

The global interrupt control registers are designed to enable software to quickly configure multiple pins within the one port for the same interrupt configuration. However, the pin control functions cannot be configured using the global interrupt control registers.

The global interrupt control registers are write-only registers and always read as 0.

### **12.6.4 External interrupts**

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin or at the output of the digital input filter, if the digital input digital filter is enabled. When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT\_ISFR or PORT\_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

### 12.6.5 Digital filter

The digital filter capabilities of the PORT module are available in all digital Pin Muxing modes if the PORT module is enabled.

The clock used for all digital filters within one port can be configured between the bus clock or the LPO clock. This selection must be changed only when all digital filters for that port are disabled. If the digital filters for a port are configured to use the bus clock, then the digital filters are bypassed for the duration of Stop mode. While the digital filters are bypassed, the output of each digital filter always equals the input pin, but the internal state of the digital filters remains static and does not update due to any change on the input pin.

The filter width in clock size is the same for all enabled digital filters within one port and must be changed only when all digital filters for that port are disabled.

The output of each digital filter is logic zero after system reset and whenever a digital filter is disabled. After a digital filter is enabled, the input is synchronized to the filter clock, either the bus clock or the LPO clock. If the synchronized input and the output of the digital filter remain different for a number of filter clock cycles equal to the filter width register configuration, then the output of the digital filter updates to equal the synchronized filter input.

The maximum latency through a digital filter equals three filter clock cycles plus the filter width configuration register.

# Chapter 13

## General-Purpose Input/Output (GPIO)

### 13.1 Chip-specific GPIO information

#### 13.1.1 Instantiation information

Port control and interrupt module features are supported, each 32-pin port will support a single interrupt. Not all pins are available on each package supported. See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for the details on which pins are supported in different packages. See [Port Control and Interrupts \(PORT\)](#) for details of how to control the ports.

See [Module operation in available power modes](#) for details on available power modes.

#### 13.1.2 GPIO ports memory map

This chip implements five instances of GPIOs GPIOA to GPIOE. The [GPIO register descriptions](#) in this chapter are generic. Refer to the table below to see how addresses are allocated to every instance of GPIO in the device memory map.

**Table 13-1. GPIO ports memory map**

| Start address | Port   |
|---------------|--------|
| Base + 0h     | Port A |
| Base + 40h    | Port B |
| Base + 80h    | Port C |
| Base + C0h    | Port D |
| Base + 100h   | Port E |

#### NOTE

- In S32K14x, GPIO can only be accessed by the core through the cross bar interface at 0x400F\_F000.

- In S32K11x, GPIO is multi-ported and can be accessed directly by the core with zero wait states at base address  $[0xF800\_0000 + 0x40*n]$  (n: 0 to 4). It can also be accessed by the core through the cross bar/AIPS interface at  $[0x400F\_F000 + 0x40*n]$  (n: 0 to 4) and at an aliased slot (15) at address  $[0x4000\_F000 + 0x40*n]$  (n: 0 to 4).
- In S32K11x, when in GPIO mode (PORT\_PCRn[MUX] programmed to 0x1), the register PIDR cannot be written to 0x1. This programming helps to disable the input mode and this is not possible to achieve in S32K11x. The implication of this is that when the GPIO is configured in output mode (PDDR[n] programmed to 1), the data written on PDOR register would be reflected on PDIR after some delay if the output does not toggle to often. If the pad needs to be tri-stated, the PORT\_PCRn[MUX] needs to be 00.

|         | GPIO at 0x400FF000         | GPIO at 0x4000F000         | GPIO at 0xF8000000     |
|---------|----------------------------|----------------------------|------------------------|
| S32K14x | Accessible in CPO mode     | NA                         | NA                     |
| S32K11x | Not accessible in CPO mode | Not accessible in CPO mode | Accessible in CPO mode |

### 13.1.3 GPIO register reset values

Following table defines the chip-specific register reset value.

**Table 13-2. GPIO register reset values**

| Register | Reset value |
|----------|-------------|
| PDIR     | 0000_0020   |

## 13.2 Introduction

The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface for maximum pin performance. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

### 13.2.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers
- Port Data Direction register

#### NOTE

The GPIO module is clocked by system clock.

### 13.2.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 13-3. Modes of operation**

| Modes of operation | Description                        |
|--------------------|------------------------------------|
| Run                | The GPIO module operates normally. |
| Stop               | The GPIO module is disabled.       |
| Debug              | The GPIO module operates normally. |

### 13.2.3 GPIO signal descriptions

**Table 13-4. GPIO signal descriptions**

| GPIO signal descriptions | Description                  | I/O |
|--------------------------|------------------------------|-----|
| PORTA31–PORTA0           | General-purpose input/output | I/O |
| PORTB31–PORTB0           | General-purpose input/output | I/O |
| PORTC31–PORTC0           | General-purpose input/output | I/O |
| PORTD31–PORTD0           | General-purpose input/output | I/O |
| PORTE31–PORTE0           | General-purpose input/output | I/O |

#### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

### 13.2.3.1 Detailed signal description

**Table 13-5. GPIO interface-detailed signal descriptions**

| Signal                                                                                 | I/O | Description                  |                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                        |     | State meaning                | Asserted: The pin is logic 1.<br>Deasserted: The pin is logic 0.                                                                                                                                                                                                                                                                                                                   |
|                                                                                        |     | Timing                       | Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.<br><br>Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. |

#### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 13.3 Memory map and register definition

The registers for each GPIO port occupy 64-byte of the memory map. Any read or write access to the GPIO slot outside this space results in a bus error.

#### NOTE

For simplicity, each GPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the chip-specific GPIO information to see the exact control bits for each port.

### 13.3.1 GPIO register descriptions

### 13.3.1.1 GPIO memory map

GPIOA base address: 400F\_F000h

GPIOB base address: 400F\_F040h

GPIOC base address: 400F\_F080h

GIOD base address: 400F\_F0C0h

GPIOE base address: 400F\_F100h

| Offset | Register                                            | Width<br>(In bits) | Access | Reset value |

13.3.1.8.4 Fields

| Field       | Function                                                                                                                                                                                                                                                |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>PID | Port Input Disable<br><br>0b - Pin is configured for General Purpose Input, provided the pin is configured for any digital function.<br>1b - Pin is not configured as General Purpose Input. Corresponding Port Data Input Register bit will read zero. |

13.4 Functional description

13.4.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the corresponding bit in the port input enable register is set, the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

13.4.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

| If                                                                                                         | Then                                                                                                                       |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| A pin is configured for the GPIO function and the corresponding port data direction register bit is clear. | The pin is configured as an input.                                                                                         |
| A pin is configured for the GPIO function and the corresponding port data direction register bit is set.   | The pin is configured as an output and the logic state of the pin is equal to the corresponding port data output register. |

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

# Chapter 14

## Crossbar Switch Lite (AXBS-Lite)

### 14.1 Chip-specific AXBS-Lite information

#### 14.1.1 Crossbar Switch master assignments

The following table identifies the masters connected to the Crossbar Switch and their priority order in fixed-priority mode.

**Table 14-1. Master port assignments and priority order for fixed-priority arbitration**

| Chips    | Master port number 0    | Master port number 1    | Master port number 2    | Master port number 3    |
|----------|-------------------------|-------------------------|-------------------------|-------------------------|
|          | Priority 3 <sup>1</sup> | Priority 2 <sup>1</sup> | Priority 1 <sup>1</sup> | Priority 4 <sup>1</sup> |
| S32K148  | Arm core code bus       | Arm core system bus     | DMA                     | ENET                    |
| S32K146  | Arm core code bus       | Arm core system bus     | DMA                     | -                       |
| S32K144  | Arm core code bus       | Arm core system bus     | DMA                     |                         |
| S32K144W | Arm core code bus       | Arm core system bus     | DMA                     |                         |
| S32K142  | Arm core code bus       | Arm core system bus     | DMA                     |                         |
| S32K116  | Arm core master bus     | -                       | DMA                     |                         |
| S32K118  | Arm core master bus     | -                       | DMA                     |                         |

1. Priority in fixed-priority mode. MCM controls mode selection for global slave port arbitration. For fixed priority, set MCM\_CPCR[CBRR] to 0. For round robin, set MCM\_CPCR[CBRR] to 1. The arbitration setting applies to all slave ports.

#### NOTE

For configuring the bit field MCM\_CPCR[CBRR], see the note present in the [CBRR](#).

#### 14.1.2 Crossbar Switch slave assignments

The following table identifies the slaves connected to the Crossbar Switch and whether the system MPU protects them.

**Table 14-2. Slave port assignments and system MPU protection**

| Chips    | Slave port number 0                  | Slave port number 1           | Slave port number 2                       | Slave port number 3  |
|----------|--------------------------------------|-------------------------------|-------------------------------------------|----------------------|
| S32K148  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> | QuadSPI <sup>1</sup> |
| S32K146  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> | -                    |
| S32K144  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> |                      |
| S32K144W | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> |                      |
| S32K142  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> |                      |
| S32K116  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> |                      |
| S32K118  | Flash memory controller <sup>1</sup> | SRAM controllers <sup>1</sup> | Peripheral Bridge 0/<br>GPIO <sup>2</sup> |                      |

1. Protected by system MPU

2. Not protected by system MPU: System MPU does not protect access to peripheral registers, including system MPU's own registers. Protection is built into Peripheral Bridge (AIPS-Lite).

## 14.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows up to four bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave.

### 14.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
- Up to single-clock 32-bit transfer
- Programmable configuration for fixed-priority or round-robin slave port arbitration (see the chip-specific information).

## 14.3 Functional Description

Information about general operation and arbitration can be found here.

### 14.3.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it remains parked with the last master to use the slave port. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port.

### 14.3.2 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The selection of the global slave port arbitration algorithm is described in the crossbar switch chip-specific information.

### 14.3.2.1 Arbitration during undefined length bursts

Undefined length bursts can be interrupted.

### 14.3.2.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level with the highest numbered master having the highest priority (for example, in a system with 5 masters, master 1 has lower priority than master 3). If two masters request access to the same slave port, the master with the highest priority gains control over the slave port.

#### NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

**Table 14-3. How the Crossbar Switch grants control of a slave port to a master**

| When                                                                                                                                                                                                                                           | Then the Crossbar Switch grants control to the requesting master                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both of the following are true: <ul style="list-style-type: none"> <li>The current master is not running a transfer.</li> <li>The new requesting master's priority level is higher than that of the current master.</li> </ul>                 | At the next clock edge                                                                                                                                                                      |
| Both of the following are true: <ul style="list-style-type: none"> <li>The current master is running an undefined length burst transfer.</li> <li>The requesting master's priority level is higher than that of the current master.</li> </ul> | At the next arbitration point for the undefined length burst transfer                                                                                                                       |
| The requesting master's priority level is lower than the current master.                                                                                                                                                                       | At the conclusion of one of the following cycles: <ul style="list-style-type: none"> <li>An IDLE cycle</li> <li>A non-IDLE cycle to a location other than the current slave port</li> </ul> |

### 14.3.2.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

The round-robin arbitration mode generally provides a more fair allocation of the available slave-port bandwidth (compared to fixed priority) as the fixed master priority does not affect the master selection.

## 14.4 Initialization/application information

No initialization is required for the crossbar switch.

# Chapter 15

## Memory Protection Unit (MPU)

### 15.1 Chip-specific MPU information

On this device, NXP's system MPU implements the safety mechanisms to prevent masters from accessing restricted memory regions. This system MPU provides memory protection at the level of the Crossbar Switch. Each Crossbar master (Core, DMA, Ethernet) can be assigned different access rights to each protected memory region. The Arm M4 and M0+ core version in this family does not integrate the Arm Core MPU, which would concurrently monitor only core-initiated memory accesses. In this document, the term MPU refers to NXP's system MPU.

#### NOTE

RGD0\_WORD2[M1PE] bit field is not used in S32K116 and S31K118.

#### 15.1.1 MPU Slave Port Assignments

The memory-mapped resources protected by the MPU are:

**Table 15-1. MPU Slave Port Assignments For S32K14x and S32K14xW series**

| Source                | MPU Slave Port Assignment | Destination      |
|-----------------------|---------------------------|------------------|
| Crossbar slave port 0 | MPU slave port 0          | Flash Controller |
| Crossbar slave port 1 | MPU slave port 1          | SRAM backdoor    |
| Code Bus              | MPU slave port 2          | SRAM_L frontdoor |
| System Bus            | MPU slave port 3          | SRAM_U frontdoor |
| Crossbar slave port 3 | MPU Slave port 4          | QuadSPI          |

**Table 15-2. MPU Slave Port Assignments for S32K11x series**

| Source                | MPU Slave Port Assignment | Destination                 |
|-----------------------|---------------------------|-----------------------------|
| Crossbar slave port 0 | MPU slave port 0          | Flash Controller            |
| Crossbar slave port 1 | MPU slave port 1          | SRAM controller/MTB_RAM/MCM |

## 15.1.2 MPU Logical Bus Master Assignments

The logical bus master assignments for the MPU are:

**Table 15-3. MPU Logical Bus Master Assignments**

| MPU Logical Bus Master ID | Bus Master                                                                                | Possible access types |            |      |             |      |       |         | PID available |
|---------------------------|-------------------------------------------------------------------------------------------|-----------------------|------------|------|-------------|------|-------|---------|---------------|
|                           |                                                                                           | User                  | Supervisor | Data | Instruction | Read | Write | Execute |               |
| 0                         | Core                                                                                      | ✓                     | ✓          | ✓    | ✓           | ✓    | ✓     | ✓       | ✓             |
| 1                         | Debugger                                                                                  | ✓                     | ✓          | ✓    | ✓           | ✓    | ✓     | ✓       | ✓             |
| 2                         | DMA                                                                                       | -                     | ✓          | ✓    | -           | ✓    | ✓     | -       | -             |

| 4-7                       | Not implemented. The region descriptor register fields for these master IDs are Reserved. |                       |            |      |             |      |       |         |               |

## 15.1.3 Current PID

Current PID is configured at Miscellaneous Control Module Process ID register (MCM\_PID).

## 15.1.4 Region descriptors and slave port configuration

For each chip in the product series, the following table shows the numbers of region descriptors and slave ports as well as the reset value of [Control/Error Status Register \(CESR\)](#) that reflects those numbers.

**Table 15-4. MPU configurations**

| Chips   | Region descriptors | Slave ports | CESR reset value |
|---------|--------------------|-------------|------------------|
| S32K116 | 8                  | 2           | 0081_2001        |
| S32K118 | 8                  | 2           | 0081_2001        |
| S32K142 | 8                  | 4           | 0081_4001h       |

*Table continues on the next page...*

**Table 15-4. MPU configurations (continued)**

| <b>Chips</b> | <b>Region descriptors</b> | <b>Slave ports</b> | <b>CESR reset value</b> |
|--------------|---------------------------|--------------------|-------------------------|
| S32K144      | 8                         | 4                  | 0081_4001h              |
| S32K144W     | 8                         | 4                  | 0081_4001h              |
| S32K146      | 8                         | 4                  | 0081_4001h              |
| S32K148      | 16                        | 5                  | 0081_5201h              |

## 15.2 Introduction

The memory protection unit (MPU) provides hardware access control for all memory references generated in the device.

## 15.3 Overview

The MPU concurrently monitors all system bus transactions and evaluates their appropriateness using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with a protection error response.

### 15.3.1 Block diagram

A simplified block diagram of the MPU module is shown in the following figure.

**Figure 15-1. MPU block diagram**

The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and the access protection error. For details of the access evaluation macro, see [Access evaluation macro](#).

## 15.3.2 Features

The MPU implements a two-dimensional hardware array of memory region descriptors and the crossbar slave ports to continuously monitor the legality of every memory reference generated by each bus master in the system.

The feature set includes:

- 16 program-visible 128-bit region descriptors, accessible by four 32-bit words each
  - Each region descriptor defines a modulo-32 byte space, aligned anywhere in memory

- Region sizes can vary from 32 bytes to 4 Gbytes
- Two access control permissions defined in a single descriptor word
  - Masters 0–3: read, write, and execute attributes for supervisor and user accesses
  - Masters 4–7: read and write attributes
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
- Alternate programming model view of the access control permissions word
- Priority given to granting permission over denying access for overlapping region descriptors
- Detects access protection errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the MPU inhibits the bus cycle being sent to the targeted slave device.
- Error registers, per slave port, capture the last faulting address, attributes, and other information
- Global MPU enable/disable control bit

## 15.4 MPU register descriptions

The programming model is partitioned into three groups:

- Control/status registers
- The data structure containing the region descriptors
- The alternate view of the region descriptor access control values

The programming model can be referenced using only 32-bit accesses. The programming model can be accessed only in supervisor mode.

Attempted references of the following types generate an error termination:

- Non-32-bit references
- Accesses in user mode

- References to undefined—that is, reserved—addresses
- References with a non-supported access type, such as a write access to a read-only register or a read access of a write-only register

## 15.4.1 MPU memory map

MPU base address: 4000\_D000h

| Offset | Register                                                    | Width<br>(In bits) | Access | Reset value |
|--------|-------------------------------------------------------------|--------------------|--------|-------------|

## 15.4.2 Control/Error Status Register (CESR)

### 15.4.2.1 Offset

| Register | Offset |
|----------|--------|
| CESR     | 0h     |

### 15.4.2.2 Diagram

### 15.4.2.3 Fields

| Field        | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>SPERR0 | <p>Slave Port 0 Error</p> <p>Indicates a captured error in EAR0 and EDR0. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error.</p> <p>0b - No error has occurred for slave port 0.<br/>1b - An error has occurred for slave port 0.</p> |
| 30<br>SPERR1 | <p>Slave Port 1 Error</p> <p>Indicates a captured error in EAR1 and EDR1. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error.</p> <p>0b - No error has occurred for slave port 1.<br/>1b - An error has occurred for slave port 1.</p> |
| 29<br>SPERR2 | <p>Slave Port 2 Error</p> <p>Indicates a captured error in EAR2 and EDR2. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error.</p> <p>0b - No error has occurred for slave port 2.<br/>1b - An error has occurred for slave port 2.</p> |
| 28<br>SPERR3 | <p>Slave Port 3 Error</p> <p>Indicates a captured error in EAR3 and EDR3. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error.</p>                                                                                                      |

### 15.4.3 Error Address Register, slave port n (EAR0 - EAR4)

### 15.4.3.1 Offset

| Register | Offset |
|----------|--------|
| EAR0     | 10h    |
| EAR1     | 18h    |
| EAR2     | 20h    |
| EAR3     | 28h    |
| EAR4     | 30h    |

### 15.4.3.2 Function

When the MPU detects an access error on slave port n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR[SPERRn] is set. Additional information about the faulting access is captured in the corresponding EDRn at the same time. This register and the corresponding EDRn contain the most recent access error; there are no hardware interlocks with CESR[SPERRn], as the error registers are always loaded upon the occurrence of each protection violation.

### 15.4.3.3 Diagram

### 15.4.3.4 Fields

| Field | Function                                                                          |
|-------|-----------------------------------------------------------------------------------|
| 31-0  | Error Address                                                                     |
| EADDR | Indicates the reference address from slave port n that generated the access error |

## 15.4.4 Error Detail Register, slave port n (EDR0 - EDR4)

### 15.4.4.1 Offset

| Register | Offset |
|----------|--------|
| EDR0     | 14h    |
| EDR1     | 1Ch    |
| EDR2     | 24h    |
| EDR3     | 2Ch    |
| EDR4     | 34h    |

### 15.4.4.2 Function

When the MPU detects an access error on slave port n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR[SPERRn] is set. Information on the faulting address is captured in the corresponding EARN register at the same time. This register and the corresponding EARN register contain the most recent access error; there are no hardware interlocks with CESR[SPERRn] as the error registers are always loaded upon the occurrence of each protection violation.

## 15.4.5 Region Descriptor n, Word 0 (RGD0\_WORD0 - RGD15\_WORD0)

### 15.4.5.1 Offset

For n = 0 to 15:

| Register   | Offset           |
|------------|------------------|
| RGDn_WORD0 | 400h + (n × 10h) |

### 15.4.5.2 Function

The first word of the region descriptor defines the 0-modulo-32 byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn\_WORD3[VLD]).

### 15.4.5.3 Diagram

### 15.4.5.4 Fields

| Field   | Function                                                                                      |
|---------|-----------------------------------------------------------------------------------------------|
| 31-5    | Start Address                                                                                 |
| SRTADDR | Defines the most significant bits of the 0-modulo-32 byte start address of the memory region. |
| 4-0     | Reserved                                                                                      |
| —       |                                                                                               |

## 15.4.6 Region Descriptor 0, Word 1 (RGD0\_WORD1)

### 15.4.6.1 Offset

| Register   | Offset |
|------------|--------|
| RGD0_WORD1 | 404h   |

### 15.4.6.2 Function

The second word of the region descriptor defines the 31-modulo-32 byte end address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn\_WORD3[VLD]).

### 15.4.6.3 Diagram

### 15.4.6.4 Fields

| Field           | Function                                                                                                                                                                    |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5<br>ENDADDR | End Address<br>Defines the most significant bits of the 31-modulo-32 byte end address of the memory region.<br><b>NOTE:</b> The MPU does not verify that ENDADDR ≥ SRTADDR. |
| 4-0<br>—        | Reserved                                                                                                                                                                    |

## 15.4.7 Region Descriptor 0, Word 2 (RGD0\_WORD2)

### 15.4.7.1 Offset

| Register   | Offset |
|------------|--------|
| RGD0_WORD2 | 408h   |

### 15.4.7.2 Function

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses. Each of these bus masters optionally includes a process identification field (if implemented for the master) within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch
- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn\_WORD2 clear the region descriptor's valid bit (RGDn\_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

### 15.4.7.3 Diagram

## 15.4.8 Region Descriptor 0, Word 3 (RGD0\_WORD3)

### 15.4.8.1 Offset

| Register   | Offset |
|------------|--------|
| RGD0_WORD3 | 40Ch   |

### 15.4.8.2 Function

The fourth word of the region descriptor contains the optional process identifier and mask, plus the region descriptor's valid bit.

### 15.4.8.3 Diagram

### 15.4.8.4 Fields

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>PID     | Process Identifier<br>Specifies the process identifier that is included in the region hit determination if RGDn_WORD2[MxPE] is set. PIDMASK can mask individual bits in this field.                                                                                                                                                                                                                                                                   |
| 23-16<br>PIDMASK | Process Identifier Mask<br>Provides a masking capability so that multiple process identifiers can be included as part of the region hit determination. If a bit in PIDMASK is set, then the corresponding PID bit is ignored in the comparison. This field and PID are included in the region hit determination if RGDn_WORD2[MxPE] is set. For more information on the handling of the PID and PIDMASK, see "Access Evaluation - Hit Determination." |
| 15-1<br>—        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0<br>VLD         | Valid<br>Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit.                                                                                                                                                                                                                                                                                                                                                           |

## MPU register descriptions

| Field | Function                                                             |
|-------|----------------------------------------------------------------------|
|       | 0b - Region descriptor is invalid<br>1b - Region descriptor is valid |

### 15.4.9 Region Descriptor n, Word 1 (RGD1\_WORD1 - RGD15\_WORD1)

#### 15.4.9.1 Offset

For n = 1 to 15:

| Register   | Offset           |
|------------|------------------|
| RGDn_WORD1 | 404h + (n × 10h) |

#### 15.4.9.2 Function

The second word of the region descriptor defines the 31-modulo-32 byte end address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn\_WORD3[VLD]).

#### 15.4.9.3 Diagram

### 15.4.9.4 Fields

| Field           | Function                                                                                                                                                                                        |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-5<br>ENDADDR | End Address<br>Defines the most significant bits of the 31-modulo-32 byte end address of the memory region.<br><b>NOTE:</b> The MPU does not verify that $\text{ENDADDR} \geq \text{SRTADDR}$ . |
| 4-0<br>—        | Reserved                                                                                                                                                                                        |

### 15.4.10 Region Descriptor n, Word 2 (RGD1\_WORD2 - RGD15\_WORD2)

#### 15.4.10.1 Offset

For  $n = 1$  to 15:

| Register   | Offset                  |
|------------|-------------------------|
| RGDn_WORD2 | $408h + (n \times 10h)$ |

#### 15.4.10.2 Function

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses. Each of these bus masters optionally includes a process identification field (if implemented for the master) within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch

## MPU register descriptions

- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn\_WORD2 clear the region descriptor's valid bit (RGDn\_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

| 2-0<br>M0UM | Bus Master 0 User Mode Access Control<br>Defines the access controls for bus master 0 in User mode. M0UM consists of three independent bits, enabling read (r), write (w), and execute (x) permissions. In M0UM[2:0]: M0UM[2] controls read permissions, M0UM[1] controls write permissions, and M0UM[0] controls execute permissions. For each bit:<br>0b - An attempted access of that mode may be terminated with an access error (if not allowed by another descriptor) and the access not performed<br>1b - Allows the given access type to occur |

### 15.4.11 Region Descriptor n, Word 3 (RGD1\_WORD3 - RGD15\_WORD3)

#### 15.4.11.1 Offset

For n = 1 to 15:

| Register   | Offset           |
|------------|------------------|
| RGDn_WORD3 | 40Ch + (n × 10h) |

#### 15.4.11.2 Function

The fourth word of the region descriptor contains the optional process identifier and mask, plus the region descriptor's valid bit.

### 15.4.11.3 Diagram

### 15.4.11.4 Fields

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>PID     | Process Identifier<br>Specifies the process identifier that is included in the region hit determination if RGDn_WORD2[MxPE] is set. PIDMASK can mask individual bits in this field.                                                                                                                                                                                                                                                                   |
| 23-16<br>PIDMASK | Process Identifier Mask<br>Provides a masking capability so that multiple process identifiers can be included as part of the region hit determination. If a bit in PIDMASK is set, then the corresponding PID bit is ignored in the comparison. This field and PID are included in the region hit determination if RGDn_WORD2[MxPE] is set. For more information on the handling of the PID and PIDMASK, see “Access Evaluation - Hit Determination.” |
| 15-1<br>—        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0<br>VLD         | Valid<br>Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit.<br>0b - Region descriptor is invalid<br>1b - Region descriptor is valid                                                                                                                                                                                                                                                                                   |

## 15.4.12 Region Descriptor Alternate Access Control 0 (RGDAAC0)

### 15.4.12.1 Offset

| Register | Offset |
|----------|--------|
| RGDAAC0  | 800h   |

### 15.4.12.2 Function

Because software may adjust only the access controls within a region descriptor (RGDn\_WORD2) as different tasks execute, an alternate programming view of this 32-bit entity is available. Writing to this register does not affect the descriptor's valid bit.

### 15.4.12.3 Diagram

1. RGDAAC0 resets to 61F7DFh. Other RGDAACn registers reset to 0h.

### 15.4.12.4 Fields

| Field      | Function                                                                                                                                                |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>M7RE | Bus Master 7 Read Enable<br>0b - Bus master 7 reads terminate with an access error and the read is not performed<br>1b - Bus master 7 reads allowed     |

For each bit:<br>0b - An attempted access of that mode may be terminated with an access error (if not allowed by another descriptor) and the access not performed<br>1b - Allows the given access type to occur                                                                      |

## 15.4.13 Region Descriptor Alternate Access Control n (RGDAAC1 - RGDAAC15)

### 15.4.13.1 Offset

For n = 1 to 15:

| Register | Offset          |
|----------|-----------------|
| RGDAACn  | 800h + (n × 4h) |

### 15.4.13.2 Function

Because software may adjust only the access controls within a region descriptor (RGDn\_WORD2) as different tasks execute, an alternate programming view of this 32-bit entity is available. Writing to this register does not affect the descriptor's valid bit.

### 15.4.13.3 Diagram

1. RGDAAC0 resets to 61F7DFh. Other RGDAACn registers reset to 0h.

### 15.4.13.4 Fields

| Field      | Function                                                                                                                                                |

## 15.5 Functional description

In this section, the functional operation of the MPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

### 15.5.1 Access evaluation macro

The basic operation of the MPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in the following figure, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGDn) and performs two major functions:

- Region hit determination
- Detection of an access protection violation

The following figure shows a functional block diagram.

**Figure 15-2. MPU access evaluation macro**

### 15.5.1.1 Hit determination

To determine whether the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[31:5] >= RGDn_Word0[SRTADDR]) & (addr[31:5] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

where *addr* is the current reference address, *RGDn\_Word0[SRTADDR]* and *RGDn\_Word1[ENDADDR]* are the start and end addresses, and *RGDn\_Word3[VLD]* is the valid bit.

#### NOTE

The MPU does not verify that *ENDADDR*  $\geq$  *SRTADDR*.

In addition to the comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. A process identifier hit term is formed as follows:

```
pid_hit = ~RGDn_Word2[MxPE] |
((current_pid |
RGDn_Word3[PIDMASK]) == (RGDn_Word3[PID] | RGDn_Word3[PIDMASK]))
```

where the *current\_pid* is the selected process identifier from the current bus master, and *RGDn\_Word3[PID]* and *RGDn\_Word3[PIDMASK]* are the process identifier fields from region descriptor *n*. For bus masters that do not output a process identifier, the MPU forces the *pid\_hit* term to assert.

### 15.5.1.2 Privilege violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master and supervisor/user mode signals, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions as shown in the following table.

**Table 15-5. Protection violation definition**

| Description            | MxUM |   |   | Protection violation?      |
|------------------------|------|---|---|----------------------------|
|                        | r    | w | x |                            |
| Instruction fetch read | —    | — | 0 | Yes, no execute permission |
|                        | —    | — | 1 | No, access is allowed      |
| Data read              | 0    | — | — | Yes, no read permission    |
|                        | 1    | — | — | No, access is allowed      |
| Data write             | —    | 0 | — | Yes, no write permission   |
|                        | —    | 1 | — | No, access is allowed      |

### 15.5.2 Putting it all together and error terminations

For each slave port monitored, the MPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports a protection error for three conditions:

- If the access does not hit in any region descriptor, a protection error is reported.
- If the access hits in a single region descriptor and that region signals a protection violation, a protection error is reported.
- If the access hits in multiple (overlapping) regions and all regions signal protection violations, a protection error is reported.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see [Application information](#).

### 15.5.3 Power management

Disabling the MPU by clearing CESR[VLD] minimizes power dissipation. To minimize the power dissipation of an enabled MPU, invalidate unused region descriptors by clearing the associated RGDn\_Word3[VLD] bits.

## 15.6 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGDn\_Word3[VLD]. Setting CESR[VLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire MPU is disabled (CESR[VLD]=0).

### Note

If the MPU registers are protected by the MPU, a region descriptor must be set to allow access to the MPU registers if further changes are needed.

## 15.7 Application information

In an operational system, interfacing with the MPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes. (Clearing RGDn\_Word3[VLD] deletes/removes an existing memory region.)
- Altering only access privileges—To not affect the valid bit, write to the alternate version of the access control word (RGDAACn), so there are no coherency issues involved with the update. When the write completes, the memory region's access rights switch instantaneously to the new value.
- Changing a region's start and end addresses—Write a minimum of three words to the region descriptor (RGDn\_Word{0,1,3}). Word 0 and 1 redefine the start and end addresses, respectively. Word 3 re-enables the region descriptor valid bit. In most situations, all four words of the region descriptor are rewritten.

- Accessing the MPU—Allocate a region descriptor to restrict MPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and  $EARN$  and  $EDRN$  capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading  $E\{A,D\}RN$ .  $CESR[SPERR]$  signals which error registers contain captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters:

- The two processors: CP0, CP1
- Two DMA engines: DMA1, a traditional data movement engine transferring data between RAM and peripherals and DMA2, a second engine transferring data to/from the RAM only

Consider the following region descriptor assignments:

**Table 15-6. Overlapping region descriptor example**

| Region description    | RGDn |   | CP0 | CP1 | DMA1 | DMA2 |                  |
|-----------------------|------|---|-----|-----|------|------|------------------|
| CP0 code              | 0    |   | rwX | r-- | —    | —    | Flash            |
| CP1 code              | 1    |   | r-- | rwX | —    | —    |                  |
| CP0 data & stack      | 2    |   | rw- | —   | —    | —    | RAM              |
| CP0 → CP1 shared data | 2    | 3 | r-- | r-- | —    | —    |                  |
| CP1 → CP0 shared data | 4    |   |     |     |      |      |                  |
| CP1 data & stack      | 4    |   | —   | rw- | —    | —    |                  |
| Shared DMA data       | 5    |   | rw- | rw- | rw   | rw   |                  |
| MPU                   | 6    |   | rw- | rw- | —    | —    |                  |
| Peripherals           | 7    |   | rw- | rw- | rw   | —    | Peripheral space |

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map: flash, RAM, and peripheral space. Each region indicates the specific permissions for each of the four bus masters and this definition provides an appropriate set of shared, private and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1 and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the IPS bus is partitioned into two regions:

- One containing the MPU's programming model accessible only to the two processor cores
- The remaining peripheral region accessible to both processors and the traditional DMA1 master

This example shows one possible application of the capabilities of the MPU in a typical system.

## Chapter 16

# Peripheral Bridge (AIPS-Lite)

## 16.1 Chip-specific AIPS information

### 16.1.1 Instantiation information

This device contains one peripheral bridge. The peripheral access protection is supported by AIPS. The MPU will not cover peripheral access protection.

### 16.1.2 Memory maps

The peripheral bridge is used to access the registers of most of the modules on this device. See S32K1xx\_memory\_map.xlsx attached to Reference Manual for the memory slot assignment.

AIPS\_PACR0 – PACR31 refer to on platform peripherals with corresponding AIPS Peripheral bridge slot numbers from 0 -31. AIPS\_OPACR0 – OPACR95 refer to off platform peripherals with corresponding AIPS Peripheral bridge slot numbers from 32 -127. For logical master ID assignments see [MPU Logical Bus Master Assignments](#).

#### 16.1.2.1 Register reset values

The following table shows chip-specific reset values for AIPS registers:

**Table 16-1. Register reset values**

| Register | S32K116   | S32K118   | S32K142   | S32K144   | S32K144W  | S32K146   | S32K148   |
|----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| MPRA     | 7770_0000 | 7770_0000 | 7770_0000 | 7770_0000 | 7770_0000 | 7770_0000 | 7777_0000 |
| PACRA    | 5400_0000 | 5400_0000 | 5400_0000 | 5400_0000 | 5400_0000 | 5400_0000 | 5400_0000 |

### 16.1.2.2 Register information

In S32K11x, CMU0 and CMU1 reside on Off-platform slots 30 and 31 respectively, and access of the same is controlled by bits OPACRD[0:7] shown below. In S32K14x and S32K14xW variants, these bits are Reserved as show in [AIPS register descriptions](#).

**Table 16-2. OPARCD register**

| Bit fields    | S32K14x  | S32K11x                           |
|---------------|----------|-----------------------------------|
| Bitfiled[0:7] | Reserved | Bit 0: TP7 (Trusted Protect 7)    |
|               |          | Bit 1: WP7 (Write Protect 7)      |
|               |          | Bit 2: SP7 (Supervisor Protect 7) |
|               |          | Bit 3: Reserved                   |
|               |          | Bit 4: TP6 (Trusted Protect 6)    |
|               |          | Bit 5: WP6 (Write Protect 6)      |
|               |          | Bit 6: SP6 (Supervisor Protect 6) |
|               |          | Bit 7: Reserved                   |

Similarly, CMU0 and CMU1 reside on on-platform slots 30 and 31 respectively, and access of the same is controlled by bits PACRB[0:3] shown below. In S32K14x and S32K14xW variants, these bits are Reserved as show in [AIPS register descriptions](#).

**Table 16-3. PARCB register**

| Bit fields    | S32K14x  | S32K11x                        |
|---------------|----------|--------------------------------|
| Bitfiled[0:3] | Reserved | Bit 0: TP7 (Trusted Protect 7) |

*Table continues on the next page...*

**Table 16-3. PARCB register (continued)**

|            |         | Bit 2: SP7 (Supervisor Protect 7) |
|            |         | Bit 3: Reserved                   |

## 16.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 4 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

### 16.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Programming model provides memory protection functionality

### 16.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 4-KB boundaries. Each peripheral is allocated one or more 4-KB block(s) of the memory map.

## 16.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

#### 16.3.1.2 Master Privilege Register A (MPRA)

### 16.3.1.2.1 Offset

| Register | Offset |
|----------|--------|
| MPRA     | 0h     |

### 16.3.1.2.2 Function

The MPRA specifies identical 4-bit fields defining the access-privilege level associated with a bus master to various peripherals on the chip. The register provides one field per bus master.

A register field that maps to an unimplemented master or peripheral behaves as read-only-zero.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the chip-specific AIPS information.

### 16.3.1.3 Peripheral Access Control Register (PACRA)

#### 16.3.1.3.1 Offset

| Register | Offset |
|----------|--------|
| PACRA    | 20h    |

#### 16.3.1.3.2 Function

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular on-platform peripheral. The peripheral assignment to each PACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

Every PACR field to which no peripheral is assigned is reserved. Reads to reserved locations return zeros, and writes are ignored.

### 16.3.1.4 Peripheral Access Control Register (PACRB)

#### 16.3.1.4.1 Offset

| Register | Offset |
|----------|--------|
| PACRB    | 24h    |

#### 16.3.1.4.2 Function

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular on-platform peripheral. The peripheral assignment to each PACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

Every PACR field to which no peripheral is assigned is reserved. Reads to reserved locations return zeros, and writes are ignored.

## 16.3.1.5 Peripheral Access Control Register (PACRD)

### 16.3.1.5.1 Offset

| Register | Offset |
|----------|--------|
| PACRD    | 2Ch    |

### 16.3.1.5.2 Function

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular on-platform peripheral. The peripheral assignment to each PACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

Every PACR field to which no peripheral is assigned is reserved. Reads to reserved locations return zeros, and writes are ignored.

## 16.3.1.6 Off-Platform Peripheral Access Control Register (OPACRA)

### 16.3.1.6.1 Offset

| Register | Offset |
|----------|--------|
| OPACRA   | 40h    |

### 16.3.1.6.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.7 Off-Platform Peripheral Access Control Register (OPACRB)

#### 16.3.1.7.1 Offset

| Register | Offset |
|----------|--------|
| OPACRB   | 44h    |

#### 16.3.1.7.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

## 16.3.1.8 Off-Platform Peripheral Access Control Register (OPACRC)

### 16.3.1.8.1 Offset

| Register | Offset |
|----------|--------|
| OPACRC   | 48h    |

### 16.3.1.8.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.9 Off-Platform Peripheral Access Control Register (OPACRD)

#### 16.3.1.9.1 Offset

| Register | Offset |
|----------|--------|
| OPACRD   | 4Ch    |

#### 16.3.1.9.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.10 Off-Platform Peripheral Access Control Register (OPACRE)

#### 16.3.1.10.1 Offset

| Register | Offset |
|----------|--------|
| OPACRE   | 50h    |

#### 16.3.1.10.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.11 Off-Platform Peripheral Access Control Register (OPACRF)

#### 16.3.1.11.1 Offset

| Register | Offset |
|----------|--------|
| OPACRF   | 54h    |

#### 16.3.1.11.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

#### 16.3.1.11.3 Diagram

#### 16.3.1.11.4 Fields

| Field | Function |
|-------|----------|
| 31    | Reserved |

### 16.3.1.12 Off-Platform Peripheral Access Control Register (OPACRG)

#### 16.3.1.12.1 Offset

| Register | Offset |
|----------|--------|
| OPACRG   | 58h    |

### 16.3.1.12.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.13 Off-Platform Peripheral Access Control Register (OPACRH)

#### 16.3.1.13.1 Offset

| Register | Offset |
|----------|--------|
| OPACRH   | 5Ch    |

#### 16.3.1.13.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.14 Off-Platform Peripheral Access Control Register (OPACRI)

#### 16.3.1.14.1 Offset

| Register | Offset |
|----------|--------|
| OPACRI   | 60h    |

### 16.3.1.14.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.15 Off-Platform Peripheral Access Control Register (OPACRJ)

#### 16.3.1.15.1 Offset

| Register | Offset |
|----------|--------|
| OPACRJ   | 64h    |

#### 16.3.1.15.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.16 Off-Platform Peripheral Access Control Register (OPACRK)

#### 16.3.1.16.1 Offset

| Register | Offset |
|----------|--------|
| OPACRK   | 68h    |

#### 16.3.1.16.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

### 16.3.1.17 Off-Platform Peripheral Access Control Register (OPACRL)

#### 16.3.1.17.1 Offset

| Register | Offset |
|----------|--------|
| OPACRL   | 6Ch    |

#### 16.3.1.17.2 Function

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

## 16.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

### 16.4.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

# Chapter 17

## Direct Memory Access Multiplexer (DMAMUX)

### 17.1 Chip-specific DMAMUX information

#### 17.1.1 Number of channels

The number of channels across S32K1xx and S32K14xW series varies across variants. See below table for the same.

**Table 17-1. Number of channles**

| Chips    | Number of channels |
|----------|--------------------|
| S32K116  | 4                  |
| S32K118  | 4                  |
| S32K142  | 16                 |
| S32K142W | 16                 |
| S32K144  | 16                 |
| S32K144W | 16                 |
| S32K146  | 16                 |
| S32K148  | 16                 |

#### 17.1.2 DMA transfers via TRGMUX trigger

The triggers from TRGMUX module can trigger a DMA transfer on the first four DMA channels, for example, the LPIT can trigger DMA via TRGMUX. See [Figure 19-2](#) for module interconnectivity details. The LPIT/DMA periodic trigger assignments are detailed at [LPIT/DMA Periodic Trigger Assignments](#).

Asynchronous DMA operation does not support trigger options.

In cases where multiple DMA request are routed to DMAMUX source, software needs to make sure that only one DMA request is enabled at a time. For example DMA request of one Ethernet timer can be enabled at a particular time, while others can enable interrupt during that time.

## 17.2 Introduction

### 17.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. See the chip-specific information to know the detailed source numbers. This process is illustrated in the following figure.

Figure 17-1. DMAMUX block diagram

### 17.2.2 Features

The DMAMUX module provides these features:

- Up to 61 peripheral slots and up to 2 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

### 17.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done by an external periodic interrupt timer (for example, PIT). This mode is available only for channels 0–3.

## 17.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

### 17.3.1 DMAMUX register descriptions

### 17.3.1.1 DMAMUX memory map

DMAMUX base address: 4002\_1000h

| Offset  | Register                                                          | Width<br>(In bits) | Access | Reset value |
|---------|-------------------------------------------------------------------|--------------------|--------|-------------|
| 0h - Fh | <a href="#">Channel Configuration register (CHCFG0 - CHCFG15)</a> | 8                  | RW     | 00h         |

### 17.3.1.2 Channel Configuration register (CHCFG0 - CHCFG15)

#### 17.3.1.2.1 Offset

For a = 0 to 15:

| Register | Offset        |
|----------|---------------|
| CHCFGa   | 0h + (a × 1h) |

#### 17.3.1.2.2 Function

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

#### NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

#### 17.3.1.2.3 Diagram

### 17.3.1.2.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                  |

## 17.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

### 17.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by an external periodic interrupt timer (for example, PIT); as such, the configuration of the periodic triggering interval is done via configuring the external periodic timer.

## Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

**Figure 17-2. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 17-3. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 17-4. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

## 17.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

## 17.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 2 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

## 17.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 17.5.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 17.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

**NOTE**

The following is an example. See the chip-specific information for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

**NOTE**

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000 /* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
```

```
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
```

## Initialization/application information

```
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

# Chapter 18

## Enhanced Direct Memory Access (eDMA)

### 18.1 Chip-specific eDMA information

Wait mode is not supported. See [Module operation in available low power modes](#) for details on available power modes.

16-byte burst and 32-byte burst is not supported on S32K11x variants.

#### 18.1.1 Seamless eDMA transfer

For S32K11x variants, there are two options to make DMA transfers seamless:

**Option 1:** When executing a large, zero wait-stated memory-to-memory transfer (as an example transfers greater than 16 MB of transfer size), insert bandwidth control using the TCD\_CSR[BWC] bits to avoid:

- Starvation of another master accessing the memory
- Any delay in writing a TCD during the transfer

#### NOTE

- This option always adds wait states for every DMA transfer.
- Without following this option, the software code working properly on S32K14x and S32K14xW devices might fail on S32K11x devices.

**Option 2:** For S32K11x devices, crossbar must be programmed to round-robin arbitration (configuring [MCM\\_CPCR\[CBRR\]](#) as '1') for seamless DMA transfers. This option affects all master configurations on the crossbar.

**NOTE**

- No bandwidth control insertion is needed in this option.
- This option works seamlessly for S32K14x and S32K14xW devices also.

## 18.1.2 Number of channels

The number of channels across the series varies across variants. See below table for the same.

**Table 18-1. Number of channles**

| Chips    | Number of channels |
|----------|--------------------|
| S32K116  | 4                  |
| S32K118  | 4                  |
| S32K142  | 16                 |
| S32K142W | 16                 |
| S32K144  | 16                 |
| S32K144W | 16                 |
| S32K146  | 16                 |
| S32K148  | 16                 |

## 18.2 Overview

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

### 18.2.1 Block diagram

The following figure illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 18-1. Block diagram

## 18.2.2 Block parts

The eDMA module comprises two major modules: the eDMA engine and the transfer-control descriptor local memory.

Table 18-2 describes the eDMA engine submodules.

Table 18-2. eDMA engine submodules

| Submodule    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address path | <p>The address path block:</p> <ul style="list-style-type: none"> <li>Provides registered versions of two channel Transfer Control Descriptors (TCDs)—channel x (normal start) and channel y (preemption start)</li> <li>Manages all master bus-address calculations</li> </ul> <p>All channels provide the same functionality. This structure enables preemption of data transfers associated with an active channel (after completion of a read/write sequence) if the eDMA engine asserts a higher priority channel activation.</p> |

Table continues on the next page...

**Table 18-2. eDMA engine submodules (continued)**

| Submodule                                 | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | <p>After eDMA activates a channel, it runs until the minor loop completes, unless preempted by a higher priority channel. This provides a mechanism (enabled by <a href="#">DCHPRI<sub>n</sub>[ECP]</a>) in which the eDMA engine can preempt a large data move operation to minimize the time another channel stalls.</p> <p>When the eDMA engine selects a channel to execute, it reads the contents of the channel TCD from local memory and loads it into one of the following:</p> <ul style="list-style-type: none"> <li>• The address path channel x registers (normal start)</li> <li>• The address path channel y registers (preemption start)</li> </ul> <p>After the minor loop execution completes, the address path hardware writes the new values for the TCD<sub>n</sub>{SADDR, DADDR, CITER} back to local memory. If the major iteration count completes, the eDMA engine performs additional processing, including:</p> <ul style="list-style-type: none"> <li>• Final address pointer updates</li> <li>• Reloading the TCD<sub>n</sub>_CITER field</li> <li>• A possible fetch of the next TCD<sub>n</sub> from memory as part of a scatter/gather operation.</li> </ul> |
| Data path                                 | <p>The data path block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase). The data path module implements the second stage of the pipeline (data phase).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The eDMA peripheral request inputs and interrupt request outputs also connect to this block (via control logic).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Control                                   | <p>The control block provides all control functions for the eDMA engine. For data transfers in which the source size (SSIZE) and destination size (DSIZE) are equal, the eDMA engine performs a series of source read/destination write operations until it has transferred the number of bytes specified in the minor loop byte count (NBYTES). For TCDs in which the source and destination sizes are not equal, the eDMA engine executes multiple accesses of the smaller size data for each reference of the larger size. For example, if the source size (SSIZE) references 16-bit data and the destination size (DSIZE) is 32-bit data, eDMA performs two reads, then one 32-bit write.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

[Table 18-3](#) explains the partitioning of the TCD local memory.

**Table 18-3. Transfer control descriptor memory**

| Submodule         | Description                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory controller | The Memory controller logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. If simultaneous accesses occur, the eDMA engine receives priority and the peripheral transaction stalls. |
| Memory array      | The Memory array provides TCD storage for the transfer profile for each channel.                                                                                                                                                                                                    |

### 18.2.3 Features

The eDMA module is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. Use it for applications where you statically know the size of the data to be transferred and do not define the size within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 16-channel implementation performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch (AXBS) for bus mastering the data movement
- TCD supports two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion notification via programmable interrupt requests
  - One interrupt per channel. eDMA engine can generate an interrupt when major iteration count completes
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

**NOTE**

In the discussion of this module,  $n$  is the channel number.

## 18.3 Memory map/register definition

The eDMA programming model consists of registers that provide:

- Control and status functions
- Channel configuration functions
- TCD definition functions

### 18.3.1 TCD memory

Each channel requires a 32-byte TCD to define the desired data movement operation. The channel descriptors are in local memory in sequential order: channel 0, channel 1, ... channel 15. Each TCD $n$  definition comprises 11 registers of 16 or 32 bits.

### 18.3.2 TCD initialization

Before activating a channel, you must initialize its TCD with the appropriate transfer profile.

### 18.3.3 TCD structure

### 18.3.4 Reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- The eDMA ignores writes to reserved bits in a register.
- Reading or writing a reserved memory location generates a bus error.

### 18.3.5 DMA register descriptions

#### 18.3.5.1 DMA memory map

DMA base address: 4000\_8000h

| Offset | Register                             | Width<br>(In bits) | Access | Reset value                |
|--------|--------------------------------------|--------------------|--------|----------------------------|

## 18.3.5.2 Control (CR)

### 18.3.5.2.1 Offset

| Register | Offset |
|----------|--------|
| CR       | 0h     |

### 18.3.5.2.2 Function

This register defines the basic operating configuration of the eDMA module.

You can configure arbitration to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, eDMA selects and executes the highest-priority channel that requests service. The channel priority registers assign the priorities (see the [Channel Priority \(DCHPRI0 - DCHPRI15\)](#) registers). For round-robin arbitration, the eDMA engine ignores channel priorities and cycles through channels from high to low channel number without regard to priority.

**NOTE**

For correct operation, you must write to this register only when the eDMA channels are inactive—that is, when  $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$ .

Minor loop offsets are address-offset values to be added to the final source address ( $\text{TCDn\_SADDR}$ ) or destination address ( $\text{TCDn\_DADDR}$ ) when the minor loop completes. When you enable minor loop offsets, eDMA adds the minor loop offset ( $\text{MLOFF}$ ) value to the final source address ( $\text{TCDn\_SADDR}$ ), to the final destination address ( $\text{TCDn\_DADDR}$ ), or to both, before it writes the addresses back into the TCD. If the major loop is complete, eDMA ignores the minor loop offset, and uses the major loop address offsets ( $\text{TCDn\_SLAST}$  and  $\text{TCDn\_DLAST\_SGA}$ ) to compute the next  $\text{TCDn\_SADDR}$  and  $\text{TCDn\_DADDR}$  values.

Enabling minor loop mapping ( $\text{EMLM} = 1$ ) redefines  $\text{TCDn}$  word2. eDMA uses a portion of  $\text{TCDn}$  word2 for multiple fields:

- A source enable field ( $\text{SMLOE}$ ) to specify the minor loop offset is to be applied to the source address ( $\text{TCDn\_SADDR}$ ) when the minor loop completes
- A destination enable field ( $\text{DMLOE}$ ) to specify the minor loop offset to be applied to the destination address ( $\text{TCDn\_DADDR}$ ) when the minor loop completes
- The sign extended minor loop offset value ( $\text{MLOFF}$ ).

eDMA uses the same offset value ( $\text{MLOFF}$ ) for both source and destination minor loop offsets. When you enable either minor loop offset ( $\text{SMLOE} = 1$  or  $\text{DMLOE} = 1$ ), the  $\text{NBYTES}$  field reduces in size to 10 bits. When you disable both minor loop offsets ( $\text{SMLOE} = 0$  and  $\text{DMLOE} = 0$ ), the  $\text{NBYTES}$  field is a 30-bit vector.

When you disable minor loop mapping ( $\text{EMLM} = 0$ ), the  $\text{NBYTES}$  field contains all 32 bits of  $\text{TCDn}$  word2.

### 18.3.5.2.3 Diagram

### 18.3.5.2.4 Fields

| Field        | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 7<br>EMLM | <p>Enable Minor Loop Mapping</p> <p>When the value of this field is 0, TCDn.word2 is a 32-bit NBYTES field. When the value of this field is 1, TCDn.word2 includes:</p> <ul style="list-style-type: none"> <li>• Individual enable fields</li> <li>• An offset field</li> <li>• The NBYTES field.</li> </ul> <p>The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field reduces in size when either offset is enabled.</p> <p>0b - Disabled<br/>1b - Enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 6<br>CLM  | <p>Continuous Link Mode</p> <p>When the value of this field is 0, a minor loop channel link made to itself goes through channel arbitration before being activated again. When the value of this field is 1, a minor loop channel link made to itself does not go through channel arbitration before being activated again. When the minor loop completes, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.</p> <p><b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.</p> <p>0b - Continuous link mode is off<br/>1b - Continuous link mode is on</p> |
| 5<br>HALT | <p>Halt eDMA Operations</p> <p>When this field is 1 the following actions take place:</p> <ul style="list-style-type: none"> <li>• eDMA stalls the start of any new channels</li> <li>• Executing channels are allowed to complete.</li> </ul> <p>When you write 0 to this field, channel execution resumes.</p> <p>0b - Normal operation<br/>1b - eDMA operations halted</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 0<br>— | Reserved                                                                                                                                                                                                                                                                                                                       |

### 18.3.5.3 Error Status (ES)

#### 18.3.5.3.1 Offset

| Register | Offset |
|----------|--------|
| ES       | 4h     |

#### 18.3.5.3.2 Function

The ES register provides information concerning the most-recently recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor
  - An illegal priority register setting in fixed arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error field that is 1 when a transfer is canceled via the corresponding cancel transfer control field

See [Fault reporting and handling](#) for more details.

### 18.3.5.4 Enable Request (ERQ)

#### 18.3.5.4.1 Offset

| Register | Offset |
|----------|--------|
| ERQ      | Ch     |

#### 18.3.5.4.2 Function

The ERQ register provides a bit map for the 16 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request field must be set to 1 before a channel's hardware service request is accepted. The state of the DMA enable request field does not affect a channel service request made explicitly through software or a linked channel request.

#### NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

### 18.3.5.5 Enable Error Interrupt (EEI)

#### 18.3.5.5.1 Offset

| Register | Offset |
|----------|--------|
| EEI      | 14h    |

#### 18.3.5.5.2 Function

The EEI register provides a bit map for the 16 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI registers. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable field must be set to 1 before an error interrupt request for a given channel is sent to the interrupt controller.

### 18.3.5.6 Clear Enable Error Interrupt (CEEI)

#### 18.3.5.6.1 Offset

| Register | Offset |
|----------|--------|
| CEEI     | 18h    |

#### 18.3.5.6.2 Function

The CEEI provides a simple memory-mapped mechanism to write 0 to a given field in the EEI register to disable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI register to be written to 0. Writing 1 to the CAEE field provides a global clear to 0 function, forcing the EEI contents to be written to 0, disabling all DMA request inputs.

If the NOP field is written with 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 18.3.5.6.3 Diagram

|       |     |      |   |   |     |   |   |   |
|-------|-----|------|---|---|-----|---|---|---|
| Bits  | 7   | 6    | 5 | 4 | 3   | 2 | 1 | 0 |

| 3-0<br>CEEI | Clear Enable Error Interrupt<br>Writes 0 to the corresponding field in EEI                                                               |

## 18.3.5.7 Set Enable Error Interrupt (SEEI)

### 18.3.5.7.1 Offset

| Register | Offset |
|----------|--------|
| SEEI     | 19h    |

### 18.3.5.7.2 Function

The SEEI register provides a simple memory-mapped mechanism to write 1 to a given field in the EEI register to enable the error interrupt for a given channel. The data value on a register write causes the corresponding field in the EEI to be written to 1. Writing 1 to the SAAE field provides a global set to 1 function, forcing the entire EEI register contents to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 18.3.5.7.3 Diagram

### 18.3.5.7.4 Fields

| Field       | Function                                                                                                                                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation, ignore the other fields in this register                                    |
| 6<br>SAEE   | Set All Enable Error Interrupts<br>0b - Write 1 only to the EEI field specified in the SEEI field<br>1b - Writes 1 to all fields in EEI |
| 5-4<br>—    | Reserved                                                                                                                                |
| 3-0<br>SEEI | Set Enable Error Interrupt<br>Writes 1 to the corresponding field in EEI                                                                |

## 18.3.5.8 Clear Enable Request (CERQ)

### 18.3.5.8.1 Offset

| Register | Offset |
|----------|--------|
| CERQ     | 1Ah    |

### 18.3.5.8.2 Function

The CERQ provides a simple memory-mapped mechanism to write 0 to a given field in the ERQ register to disable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be written with 0. Setting the CAER field provides a global clear to 0 function, forcing the entire contents of the ERQ register to be written with 0, disabling all DMA request inputs.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

#### NOTE

Disable a channel's hardware service request at the source before writing 0 to the channel's ERQ field.

### 18.3.5.8.3 Diagram

|       |     |      |   |   |      |   |   |   |
|-------|-----|------|---|---|------|---|---|---|
| Bits  | 7   | 6    | 5 | 4 | 3    | 2 | 1 | 0 |
| R     | 0   | 0    |   |   | 0    |   |   |   |
| W     | NOP | CAER | 0 |   | CERQ |   |   |   |
| Reset | 0   | 0    | 0 | 0 | 0    | 0 | 0 | 0 |

### 18.3.5.8.4 Fields

| Field       | Function                                                                                                                         |
|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation, ignore the other fields in this register                             |
| 6<br>CAER   | Clear All Enable Requests<br>0b - Write 0 to only the ERQ field specified in the CERQ field<br>1b - Write 0 to all fields in ERQ |
| 5-4<br>—    | Reserved                                                                                                                         |
| 3-0<br>CERQ | Clear Enable Request<br>Writes 0 to the corresponding field in ERQ.                                                              |

### 18.3.5.9 Set Enable Request (SERQ)

#### 18.3.5.9.1 Offset

| Register | Offset |
|----------|--------|
| SERQ     | 1Bh    |

#### 18.3.5.9.2 Function

The SERQ provides a simple memory-mapped mechanism to write 1 to a given field in the ERQ register to enable the DMA request for a given channel. The data value on a register write causes the corresponding field in the ERQ register to be set. Writing 1 to the SAER field provides a global set to 1 function, forcing the entire contents of ERQ register to be 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register returns all zeroes.

#### 18.3.5.9.3 Diagram

| 3-0<br>SERQ | Set Enable Request<br>Writes 1 to the corresponding field in ERQ. |

## 18.3.5.10 Clear DONE Status Bit (CDNE)

### 18.3.5.10.1 Offset

| Register | Offset |
|----------|--------|
| CDNE     | 1Ch    |

### 18.3.5.10.2 Function

The CDNE provides a simple memory-mapped mechanism to write 0 to the DONE field in the TCD of the given channel. The data value on a register write causes the DONE field in the corresponding TCD to be written with 0. Writing 1 to the CADN field provides a global clear function, forcing all DONE fields to be written with 0.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 18.3.5.10.3 Diagram

### 18.3.5.10.4 Fields

| Field       | Function                                                                                                                                            |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation; all other fields in this register are ignored.                                          |

| 5-4<br>—    | Reserved                                                                                                                                            |
| 3-0<br>CDNE | Clear DONE field<br>Writes 0 to the corresponding field in TCDn_CSR[DONE]                                                                           |

## 18.3.5.11 Set START Bit (SSRT)

### 18.3.5.11.1 Offset

| Register | Offset |
|----------|--------|
| SSRT     | 1Dh    |

### 18.3.5.11.2 Function

The SSRT register provides a simple memory-mapped mechanism to write 1 to the START field in the TCD of the given channel. The data value on a register write causes the START field in the corresponding TCD to be written with 1. Writing 1 to the SAST field provides a global set to 1 function, forcing all START fields to be written with 1.

If the NOP field is 1, the command is ignored. This enables you to write 1 to a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word must all have their NOP field written with 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

### 18.3.5.11.3 Diagram

|       |     |     |   |   |     |   |   |   |

## 18.3.5.12 Clear Error (CERR)

### 18.3.5.12.1 Offset

| Register | Offset |
|----------|--------|
| CERR     | 1Eh    |

### 18.3.5.12.2 Function

The CERR provides a simple memory-mapped mechanism to write 0 to a given field in the ERR register to disable the error condition field for a given channel. The given value on a register write causes the corresponding field in the ERR register to be written with 0. Writing 1 to the CAEI field provides a global clear to 0 function, forcing the ERR register contents to be written with 0, clearing all channel error indicators. If the NOP field is 1, the command is ignored. This enables you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

### 18.3.5.12.3 Diagram

### 18.3.5.12.4 Fields

| Field       | Function                                                                                                                          |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP    | No Op Enable<br>0b - Normal operation<br>1b - No operation; all other fields in this register are ignored.                        |

| 3-0<br>CERR | Clear Error Indicator<br>Writes 0 to the corresponding field in ERR                                                               |

## 18.3.5.13 Clear Interrupt Request (CINT)

### 18.3.5.13.1 Offset

| Register | Offset |
|----------|--------|
| CINT     | 1Fh    |

### 18.3.5.13.2 Function

The CINT register provides a simple, memory-mapped mechanism to clear a given field in the INT register to disable the interrupt request for a given channel. The given value on a register write causes the corresponding field in the INT register to be cleared. Setting the CAIR field provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests.

If the NOP field is 1, the command is ignored. This enables you to set a single, byte-wide register with a 32-bit write that does not affect the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP field set to 1 so that these registers are not affected by the write.

Reads of this register return all zeroes.

## 18.3.5.14 Interrupt Request (INT)

### 18.3.5.14.1 Offset

| Register | Offset |
|----------|--------|
| INT      | 24h    |

### 18.3.5.14.2 Function

The INT register provides a bit map for the 16 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to write 0 to the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A 0 in any bit position has no effect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

### 18.3.5.15 Error (ERR)

### 18.3.5.15.1 Offset

| Register | Offset |
|----------|--------|
| ERR      | 2Ch    |

### 18.3.5.15.2 Function

The ERR register provides a bit map for the 16 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the EEI register, and then routed to the interrupt controller. During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to reset the appropriate bit to 0, negating the error-interrupt request. Typically, a write to the CERR in the interrupt service routine is used for this purpose. The normal DMA channel completion indicators (setting the TCD DONE field to 1 and the possible generation of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a 1 in any bit position clears the corresponding channel's error status. A 0 in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be reset to 0.

## 18.3.5.16 Hardware Request Status (HRS)

### 18.3.5.16.1 Offset

| Register | Offset |
|----------|--------|
| HRS      | 34h    |

### 18.3.5.16.2 Function

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals, as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

#### NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Each HRS field for its respective channel is 1 when a hardware request is present on the channel. After the request is completed and channel is free, the HRS field is automatically changed to 0 by hardware.

## 18.3.5.18 Channel Priority (DCHPRI0 - DCHPRI15)

### 18.3.5.18.1 Offset

For  $n = 0$  to 15:

| Register   | Offset                                  |
|------------|-----------------------------------------|
| DCHPRI $n$ | $100h + (n + 3 - 2 \times (n \bmod 4))$ |

### 18.3.5.18.2 Function

When fixed-priority channel arbitration is enabled ( $CR[ERCA] = 0$ ), the contents of these registers define the unique priorities associated with each channel. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

### 18.3.5.18.3 Diagram

### 18.3.5.18.4 Register reset values

| Register | Reset value |
|----------|-------------|
| DCHPRI0  | 00h         |
| DCHPRI1  | 01h         |
| DCHPRI2  | 02h         |
| DCHPRI3  | 03h         |
| DCHPRI4  | 04h         |
| DCHPRI5  | 05h         |
| DCHPRI6  | 06h         |
| DCHPRI7  | 07h         |
| DCHPRI8  | 08h         |
| DCHPRI9  | 09h         |
| DCHPRI10 | 0Ah         |
| DCHPRI11 | 0Bh         |
| DCHPRI12 | 0Ch         |
| DCHPRI13 | 0Dh         |
| DCHPRI14 | 0Eh         |
| DCHPRI15 | 0Fh         |

### 18.3.5.18.5 Fields

| Field        | Function                                                                                                                                                                                                                                   |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>ECP     | Enable Channel Preemption. This field resets to 0.<br>0b - Channel n cannot be suspended by a higher priority channel's service request<br>1b - Channel n can be temporarily suspended by the service request of a higher priority channel |
| 6<br>DPA     | Disable Preempt Ability. This field resets to 0.<br>0b - Channel n can suspend a lower priority channel<br>1b - Channel n cannot suspend any channel, regardless of channel priority                                                       |
| 5-4<br>—     | Reserved                                                                                                                                                                                                                                   |
| 3-0<br>CHPRI | Channel n Arbitration Priority<br>Channel priority when fixed-priority arbitration is enabled.                                                                                                                                             |

### 18.3.5.19 TCD Source Address (TCD0\_SADDR - TCD15\_SADDR)

#### 18.3.5.19.1 Offset

For  $n = 0$  to 15:

| Register   | Offset            |
|------------|-------------------|
| TCDn_SADDR | 1000h + (n × 20h) |

#### 18.3.5.19.2 Function

This register contains the source address of the transfer.

#### 18.3.5.19.3 Diagram

#### 18.3.5.19.4 Fields

| Field | Function                                    |
|-------|---------------------------------------------|
| 31-0  | Source Address                              |
| SADDR | Memory address pointing to the source data. |

### 18.3.5.20 TCD Signed Source Address Offset (TCD0\_SOFF - TCD15\_SOFF)

### 18.3.5.20.1 Offset

For  $n = 0$  to 15:

| Register  | Offset            |
|-----------|-------------------|
| TCDn_SOFF | 1004h + (n × 20h) |

### 18.3.5.20.2 Diagram

### 18.3.5.20.3 Fields

| Field | Function                                                                                                                  |
|-------|---------------------------------------------------------------------------------------------------------------------------|
| 15-0  | Source address signed offset                                                                                              |
| SOFF  | Sign-extended offset applied to the current source address to form the next-state value as each source read is completed. |

## 18.3.5.21 TCD Transfer Attributes (TCD0\_ATTR - TCD15\_ATTR)

### 18.3.5.21.1 Offset

For  $n = 0$  to 15:

| Register  | Offset            |
|-----------|-------------------|
| TCDn_ATTR | 1006h + (n × 20h) |

### 18.3.5.21.2 Diagram

### 18.3.5.21.3 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-11<br>SMOD | Source Address Modulo<br>Any non-zero value in this field defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.<br>00000b - Source address modulo feature is disabled<br>00001-11111b - Value defines address range used to set up circular data queue |
| 10-8<br>SSIZE | Source data transfer size<br><b>NOTE:</b> 1. Using a reserved value causes a configuration error.<br>2. The eDMA defaults to privileged data access for all transactions.<br>000b - 8-bit<br>001b - 16-bit<br>010b - 32-bit<br>011b - Reserved<br>100b - 16-byte burst<br>101b - 32-byte burst<br>110b - Reserved<br>111b - Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7-3<br>DMOD   | Destination Address Modulo<br>See the SMOD definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 2-0<br>DSIZE  | Destination data transfer size<br>See the SSIZE definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 18.3.5.22 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0\_NBYTES\_MLNO - TCD15\_NBYTES\_MLNO)

#### 18.3.5.22.1 Offset

For n = 0 to 15:

| Register         | Offset            |
|------------------|-------------------|
| TCDn_NBYTES_MLNO | 1008h + (n × 20h) |

### 18.3.5.22.2 Function

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if minor loop mapping is disabled ([CR\[EMLM\]](#) = 0).

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

| 31-0   | Minor Byte Transfer Count                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| NBYTES | <p>Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption.</p> <p>After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.</p> <p><b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.</p> |

### 18.3.5.23 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0\_NBYTES\_MLOFFNO - TCD15\_NBYTES\_MLOFFNO)

### 18.3.5.23.1 Offset

For  $n = 0$  to 15:

| Register            | Offset            |
|---------------------|-------------------|
| TCDn_NBYTES_MLOFFNO | 1008h + (n × 20h) |

### 18.3.5.23.2 Function

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled ( $CR[EMLM] = 1$ ) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE = 1 or DMLOE = 1, refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, refer to the TCD\_NBYTES\_MLNO register description.

### 18.3.5.24 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0\_NBYTES\_MLOFFYES - TCD15\_NBYTES\_MLOFFYES)

#### 18.3.5.24.1 Offset

For  $n = 0$  to 15:

| Register             | Offset            |
|----------------------|-------------------|
| TCDn_NBYTES_MLOFFYES | 1008h + (n × 20h) |

#### 18.3.5.24.2 Function

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), that defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, is enabled but not used for this channel, or is enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled ([CR\[EMLM\]](#) = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE = 1 and DMLOE = 1, refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, refer to the TCD\_NBYTES\_MLNO register description.

| SLAST | Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.<br><br>This register uses two's complement notation; the overflow bit is discarded. |

## 18.3.5.26 TCD Destination Address (TCD0\_DADDR - TCD15\_DADDR)

### 18.3.5.26.1 Offset

For n = 0 to 15:

| Register   | Offset            |
|------------|-------------------|
| TCDn_DADDR | 1010h + (n × 20h) |

### 18.3.5.26.2 Function

This register contains the destination address of the transfer.

### 18.3.5.26.3 Diagram

### 18.3.5.26.4 Fields

| Field | Function                                         |
|-------|--------------------------------------------------|
| 31-0  | Destination Address                              |
| DADDR | Memory address pointing to the destination data. |

## 18.3.5.27 TCD Signed Destination Address Offset (TCD0\_DOFF - TCD15\_DOFF)

### 18.3.5.27.1 Offset

For n = 0 to 15:

| Register  | Offset            |
|-----------|-------------------|
| TCDn_DOFF | 1014h + (n × 20h) |

### 18.3.5.27.2 Diagram

### 18.3.5.27.3 Fields

| Field | Function                                                                                                                             |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| 15-0  | Destination Address Signed Offset                                                                                                    |
| DOFF  | Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed. |

## 18.3.5.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0\_CITER\_ELINKNO - TCD15\_CITER\_ELINKNO)

### 18.3.5.28.1 Offset

For  $n = 0$  to 15:

| Register           | Offset                   |
|--------------------|--------------------------|
| TCDn_CITER_ELINKNO | $1016h + (n \times 20h)$ |

### 18.3.5.28.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as [TCD Current Minor Loop Link, Major Loop Count \(Channel Linking Enabled\) \(TCD0\\_CITER\\_ELINKYES - TCD15\\_CITER\\_ELINKYES\)](#), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 0, this register is defined as follows.

### 18.3.5.28.3 Diagram

### 18.3.5.28.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>ELINK   | <p>Enable channel-to-channel linking on minor-loop complete</p> <p>As the channel completes the minor loop, this field enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel.</p> <p>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported.</p> <p>0b - Channel-to-channel linking is disabled<br/>1b - Channel-to-channel linking is enabled</p>                                                                                           |
| 14-0<br>CITER | <p>Current Major Iteration Count</p> <p>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations. It optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.</p> <p><b>NOTE:</b></p> <ol style="list-style-type: none"> <li>When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</li> <li>If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</li> </ol> |

### 18.3.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0\_CITER\_ELINKYES - TCD15\_CITER\_ELINKYES)

#### 18.3.5.29.1 Offset

For n = 0 to 15:

| Register            | Offset            |
|---------------------|-------------------|
| TCDn_CITER_ELINKYES | 1016h + (n × 20h) |

### 18.3.5.29.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as [TCD Current Minor Loop Link, Major Loop Count \(Channel Linking Disabled\) \(TCD0\\_CITER\\_ELINKNO - TCD15\\_CITER\\_ELINKNO\)](#), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is 1, this register is defined as follows.

### 18.3.5.29.3 Diagram

### 18.3.5.29.4 Fields

| Field          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Field               | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-14<br>BWC        | <p>Bandwidth Control</p> <p>Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.</p> <p><b>NOTE:</b> If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.</p> <p>00b - No eDMA engine stalls<br/>           01b - Reserved<br/>           10b - eDMA engine stalls for 4 cycles after each R/W<br/>           11b - eDMA engine stalls for 8 cycles after each R/W</p> |
| 13-12<br>—          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 18.3.5.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0\_BITER\_ELINKNO - TCD15\_BITER\_ELINKNO)

#### 18.3.5.32.1 Offset

For n = 0 to 15:

| Register           | Offset            |
|--------------------|-------------------|
| TCDn_BITER_ELINKNO | 101Eh + (n × 20h) |

#### 18.3.5.32.2 Function

If TCDn\_BITER[ELINK] is 0, the TCDn\_BITER register is defined as follows.

#### 18.3.5.32.3 Diagram

#### 18.3.5.32.4 Fields

| Field       | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>ELINK | Enables channel-to-channel linking on minor loop complete<br>As the channel completes the minor loop, this field enables linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets TCDn_CSR[START] of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. |

## 18.4 Functional description

The operation of the eDMA is described in the following subsections.

### 18.4.1 Modes of operation

eDMA operates in the following modes:

**Table 18-4. Modes of operation**

| Mode   | Description                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal | In Normal mode, eDMA transfers data from a source to a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. |

*Table continues on the next page...*

**Table 18-4. Modes of operation (continued)**

| Mode  | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>A <i>service request</i> initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD.</p> <ul style="list-style-type: none"> <li>The <i>minor loop</i> is the sequence of read and write operations that transfers the NBYTES of data for a service request.</li> <li>Each service request executes one iteration of the major loop, transferring NBYTES of data.</li> </ul>                   |
| Debug | <p>DMA operation is configurable in Debug mode via <a href="#">Control (CR)</a></p> <ul style="list-style-type: none"> <li>If CR[EDBG] = 0, eDMA continues to operate normally when the chip is in debug mode.</li> <li>If CR[EDBG] = 1, eDMA stops transferring data when the chip enters debug mode. If a channel is active when eDMA enters Debug mode, eDMA continues operation until the channel retires.</li> </ul> |
| Wait  | <p>Before entering Wait mode, eDMA attempts to complete any transfer that is in progress. After the transfer completes, the chip enters Wait mode.</p>                                                                                                                                                                                                                                                                    |

## 18.4.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

**Figure 18-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $TCD_n\_CSR[START]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration executes, using either the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $TCD_n$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine's internal register file. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the internal register file.

The following diagram illustrates the second part of the basic data flow:

**Figure 18-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) execute sequentially through the required source reads and destination writes to perform the data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 18-4. eDMA operation, part 3

### 18.4.3 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on 0-modulo transfer size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### NOTE

When two channels have the same priority, a channel priority error exists and is reported in the Error Status register. However, the channel number is not reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control register. If all channel priorities within a group are not unique, the DMA is halted after the CPE error is recorded. The DMA remains halted and does not process any channel service requests. After all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the HALT bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[ELINK] bit does not equal the TCDn\_BITER[ELINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion, when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the

data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be canceled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the canceled channel number and ECX is set. The TCD of a canceled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is canceled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

### **NOTE**

The cancel transfer request enables you to stop a large data transfer when the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must manage the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor because the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 18.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting DCHPRIn[ECP]. Channel preemption enables the executing channel's data transfers to temporarily be suspended in favor of starting a higher priority channel. After the preempting channel has completed its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preemption ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This enables a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

## 18.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 18.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRIn registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
  - Software: setting TCDn\_CSR[START]
  - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels in the programming model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in [Table 18-5](#), for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the system bus, unless a configuration error is detected. Transfers from the source, as defined by `TCDn_SADDR`, to the destination, as defined by `TCDn_DADDR`, continue until the number of bytes specified by `TCDn_NBYTES` have been transferred.

When the transfer is complete, the eDMA engine's local `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_CITER` are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post-processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 18-5. TCD control and status fields**

| TCDn_CSR field name | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| START               | Control bit to start channel explicitly when using a software-initiated DMA service (automatically cleared by hardware) |
| ACTIVE              | Status bit indicating the channel is currently in execution                                                             |
| DONE                | Status bit indicating major loop completion (cleared by software when using a software-initiated DMA service)           |
| DREQ                | Control bit to disable DMA request at end of major loop completion when using a hardware-initiated DMA service          |
| BWC                 | Control bits for throttling bandwidth control of a channel                                                              |
| ESG                 | Control bit to enable scatter/gather feature                                                                            |
| INTHALF             | Control bit to enable interrupt when major loop is half complete                                                        |
| INTMAJOR            | Control bit to enable interrupt when major loop completes                                                               |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 18-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 18-6. Memory array terms

## 18.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than channel priority error, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting are associated with the selected channel.

## 18.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 18.5.3.1 Fixed channel arbitration

In this mode, the channel service request from the highest priority channel is selected to execute.

### 18.5.3.2 Round-robin channel arbitration

Channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels.

## 18.5.4 DMA transfer examples

This section presents examples of how to perform DMA transfers with the eDMA.

### 18.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $\text{TCDn\_CITER} = \text{TCDn\_BITER} = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete,  $\text{TCDn\_CSR}[\text{DONE}]$  is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has an 8-bit memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INTMAJOR] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the  $\text{TCDn\_CSR}[\text{START}]$  bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:  $\text{TCDn\_CSR}[\text{DONE}] = 0$ ,  $\text{TCDn\_CSR}[\text{START}] = 0$ ,  $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$ .
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

- h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
- 6. The eDMA engine writes: TCD<sub>n</sub>\_SADDR = 0x1000, TCD<sub>n</sub>\_DADDR = 0x2000, TCD<sub>n</sub>\_CITER = 1 (TCD<sub>n</sub>\_BITER).
- 7. The eDMA engine writes: TCD<sub>n</sub>\_CSR[ACTIVE] = 0, TCD<sub>n</sub>\_CSR[DONE] = 1, INT[n] = 1.
- 8. The channel retires and the eDMA goes idle or services the next channel.

### 18.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

- 1. First hardware, that is, the eDMA peripheral, requests channel service.
- 2. The channel is selected by arbitration for servicing.
- 3. eDMA engine writes: TCD<sub>n</sub>\_CSR[DONE] = 0, TCD<sub>n</sub>\_CSR[START] = 0, TCD<sub>n</sub>\_CSR[ACTIVE] = 1.
- 4. eDMA engine reads: channel TCD<sub>n</sub> data from local memory to internal register file.
- 5. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32 bits to location 0x200C → last iteration of the minor loop.
- 6. eDMA engine writes: TCD<sub>n</sub>\_SADDR = 0x1010, TCD<sub>n</sub>\_DADDR = 0x2010, TCD<sub>n</sub>\_CITER = 1.
- 7. eDMA engine writes: TCD<sub>n</sub>\_CSR[ACTIVE] = 0.

8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
12. eDMA engine reads channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 2$  ( $TCDn\_BITER$ ).
15. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

### 18.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of zero for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a  $2^4$  byte (16-byte) size queue.

**Table 18-6. Modulo example**

| Transfer number | Address    |
|-----------------|------------|
| 1               | 0x12345670 |
| 2               | 0x12345674 |
| 3               | 0x12345678 |
| 4               | 0x1234567C |
| 5               | 0x12345670 |
| 6               | 0x12345674 |

## 18.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

### 18.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests. The first is to read the `TCDn_CITER` field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test `TCDn_CSR[START]` and `TCDn_CSR[ACTIVE]`. The minor-loop-complete condition is indicated by both bits reading zero after `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCDn_CSR bits |        |      | State                                            |
|-------|---------------|--------|------|--------------------------------------------------|
|       | START         | ACTIVE | DONE |                                                  |
| 1     | 1             | 0      | 0    | Channel service request via software             |
| 2     | 0             | 1      | 0    | Channel is executing                             |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using service requests initiated by hardware, that is, peripherals, is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCDn_CSR bits |        |      | State                                                              |
|-------|---------------|--------|------|--------------------------------------------------------------------|
|       | START         | ACTIVE | DONE |                                                                    |
| 1     | 0             | 0      | 0    | Channel service request via hardware (peripheral request asserted) |
| 2     | 0             | 1      | 0    | Channel is executing                                               |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle                   |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle                   |

For both activation types, the major-loop-complete status is explicitly indicated via the TCDn\_CSR[DONE] bit.

The TCDn\_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 18.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn\_SADDR, TCDn\_DADDR, and TCDn\_NBYTES values if read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 18.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected as the channel arbitration mode. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed channel arbitration mode, determination of the actively running relative priority outstanding requests become undefined. Channel priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCDn\_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCDn\_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

## 18.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[ELINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_ELINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x3
```

executes as:

1. Minor loop done → set `TCD2_CSR[START]` bit.
2. Minor loop done → set `TCD2_CSR[START]` bit.
3. Minor loop done → set `TCD2_CSR[START]` bit.
4. Minor loop done, major loop done → set `TCD3_CSR[START]` bit.

When minor loop linking is enabled (`TCDn_CITER[ELINK] = 1`), the `TCDn_CITER[CITER]` field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (`TCDn_CITER[ELINK] = 0`), the `TCDn_CITER[CITER]` field uses a 15-bit vector to form the current iteration count. The bits associated with the `TCDn_CITER[LINKCH]` field are concatenated onto the `CITER` value to increase the range of the `CITER`.

### Note

The `TCDn_CITER[ELINK]` bit and the `TCDn_BITER[ELINK]` bit must be equal or a configuration error is reported. The `CITER` and `BITER` vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

**Table 18-7. Channel linking parameters**

| Desired link behavior     | TCD control field name | Description                                                                    |
|---------------------------|------------------------|--------------------------------------------------------------------------------|
| Link at end of minor loop | CITER[ELINK]           | Enable channel-to-channel linking on minor loop completion (current iteration) |
|                           | CITER[LINKCH]          | Link channel number when linking at end of minor loop (current iteration)      |
| Link at end of major loop | CSR[MAJOR_ELINK]       | Enable channel-to-channel linking on major loop completion                     |
|                           | CSR[MAJOR_LINKCH]      | Link channel number when linking at end of major loop                          |

## 18.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 18.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 18.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting [TCDn\\_CSR\[MAJORELINK\]](#) during channel execution (see the diagram in [TCD structure](#)). This field is read from the TCD local memory at the end of channel execution, thus enabling you to enable the feature during channel execution.

Because you can change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic channel link by enabling [TCDn\\_CSR\[MAJORELINK\]](#) at the same time the eDMA engine is retiring the channel. [TCDn\\_CSR\[MAJORELINK\]](#) would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write one to TCDn\_CSR[MAJORELINK].
2. Read back TCDn\_CSR[MAJORELINK].
3. Test the TCDn\_CSR[MAJORELINK] request status:
  - If TCDn\_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
  - If TCDn\_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces TCDn\_CSR[MAJORELINK] to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

### NOTE

You must clear [TCDn\\_CSR\[DONE\]](#) before writing TCDn\_CSR[MAJORELINK]. The eDMA engine automatically clears TCDn\_CSR[DONE] after a channel begins execution.

## 18.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It enables a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because you are able to change the configuration during execution, a coherency model is needed. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the [TCDn\\_CSR\[ESG\]](#) bit at the same time the eDMA engine is retiring the channel. The ESG bit would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the MAJORLINKCH field and the ESG bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD MAJOR[ELINK] and ESG bits to zero on any writes to a channel's TCD word 7 if that channel's TCD[DONE] bit is set, indicating the major loop is complete.

**NOTE**

The user must clear the [TCDn\\_CSR\[DONE\]](#) bit before writing the MAJORELINK or ESG bits. The TCDn\_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

**18.5.7.3.1 Method 1 (channel not using major loop channel linking)**

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When [TCDn\\_CSR\[MAJORELINK\]](#) is zero, TCDn\_CSR[MAJORLINKCH] is not used by the eDMA. In this case, MAJORLINKCH may be used for other purposes. This method uses the MAJORLINKCH field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in TCDn\_CSR[MAJORLINKCH] for each TCD associated with a channel using dynamic scatter/gather.
2. Write one to [TCDn\\_CSR\[DREQ\]](#).

Should a dynamic scatter/gather attempt fail, setting the DREQ bit prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST\_SGA final offset value.

3. Write the [TCDn\\_DLASTSGA](#) register with the scatter/gather address.
4. Write one to TCDn\_CSR[ESG].
5. Read back the 16-bit TCD control/status field.
6. Test the ESG request status and MAJORLINKCH value in the TCDn\_CSR register:

If ESG = 1, the dynamic link attempt was successful.

If ESG = 0 and MAJORLINKCH (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If ESG = 0 and MAJORLINKCH (ID) changed, the dynamic link attempt was successful (the new TCD's ESG value cleared the ESG bit).

**18.5.7.3.2 Method 2 (channel using major loop channel linking)**

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD[DLAST\_SGA] field as a TCD identification (ID).

1. Write one to [TCDn\\_CSR\[DREQ\]](#).

Should a dynamic scatter/gather attempt fail, setting TCDn\_CSR[DREQ] prevents a future hardware activation of the channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST\_SGA final offset value.

2. Write the [TCDn\\_DLAST\\_SGA](#) register with the scatter/gather address.
3. Write one to TCDn\_CSR[ESG].
4. Read back TCDn\_CSR[ESG].
5. Test the ESG request status:

If ESG = 1, the dynamic link attempt was successful.

If ESG = 0, read the 32-bit TCDn\_DLAST\_SGA field.

If ESG = 0 and TCDn\_DLAST\_SGA did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If ESG = 0 and TCDn\_DLAST\_SGA changed, the dynamic link attempt was successful (the new TCD's ESG value cleared the ESG bit).

## 18.5.8 Suspend/resume a DMA channel with active hardware service requests

The DMA enables you to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. After the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), ADC, or other module.

### 18.5.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status register (DMA\_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

### 18.5.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the relevant ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the SPI\_TXFIFO has an empty slot. The DMA transfers the next command and data to the TXFIFO upon the request. You must suspend the DMA/SPI transfer loop and perform the following steps:

1. Disable the DMA service request at the source by writing zero to SPI\_RSER[TFFF\_RE]. Confirm that SPI\_RSER[TFFF\_RE] is zero.
2. Ensure there is no DMA service request from the SPI by verifying that DMA\_HRS[HRS<sub>n</sub>] is zero for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

## Chapter 19

# Trigger MUX Control (TRGMUX)

## 19.1 Chip-specific TRGMUX information

### 19.1.1 Module interconnectivity

The TRGMUX provides an extremely flexible mechanism for connecting various trigger sources to multiple pins/peripherals.

See [Figure 19-2](#) and [Figure 19-3](#) for available input triggers.

With the TRGMUX, each peripheral that accepts external triggers usually has one specific 32-bit trigger control register. Each control register supports up to four triggers, and each trigger can be selected from the available input triggers.

The following figure shows the main structure of TRGMUX, using Module\_A as an example.

**Figure 19-1. TRGMUX structure example (64 inputs)**

### NOTE

Each TRGMUX control register supports up to four trigger channels, but each module does not necessarily implement all four triggers. Modules that need more than four trigger inputs (such as for external output) have multiple control registers.

The following figures show the superset of trigger inputs, outputs, and control registers for the S32K1xx series. See attached S32K1xx\_Trigger\_Muxing.xlsx for details on recommendations which must be adhered while using the triggering scheme.

| Trigger Source          | TRGMUX |             |                |              |       | Target Module    |
|-------------------------|--------|-------------|----------------|--------------|-------|------------------|
|                         | IN     | Pre-TRIG IN | Register       | Pre-TRIG OUT | OUT   |                  |

1 In the ADC Configuration chapter, see the "Trigger Latching and Arbitration" section for details.

2 Interrupt enable needs to be configured before expecting RTC\_alarm and RTC\_second trigger from TRGMUX.

**Figure 19-2. Trigger interconnectivity (part 1 of 2: outputs 0-63)**

<sup>1</sup> Interrupt enable needs to be configured before expecting RTC\_alarm and RTC\_second trigger from TRGMUX.

Note: Above figure shows all the connections. Slots for an absent instance in a particular part are Reserved.

**Figure 19-3. Trigger interconnectivity (part 2 of 2: outputs 64-127)**

**NOTE**

Additional details about ADC triggers include:

- For each ADC, the four triggers are ORed together to provide a flexible scheme for the hardware trigger of each ADC. The pretriggers are not ORed.
- Only LPIT supports pretriggers.
- If other peripherals require pretriggers, software pretriggers must be used. See `SIM_ADCCOPT[ADCxSWPRETRG]` for configuring software pretriggers.
- See [ADC Trigger Sources](#) for more information about ADC trigger implementation, including a PDB pretrigger scheme that does not involve TRGMUX.

### 19.1.2 TRGMUX register information

Some TRGMUX registers and input connections are present only on some S32K1xx products. Registers and input connections for instances unavailable in a particular variant are Reserved.

## 19.2 Introduction

The trigger multiplexer (TRGMUX) module allows software to configure the trigger inputs for various peripherals.

## 19.3 Features

The TRGMUX module allows software to select the trigger source for peripherals. The block diagram below shows the trigger selection logic of the TRGMUX module.

**Figure 19-4. TRGMUX block diagram**

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

## 19.4 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

### 19.4.1 TRGMUX register descriptions

#### 19.4.1.1 TRGMUX memory map

**Table 19-1. Select Bit Fields**

| Field | Description                                                                                  |
|-------|----------------------------------------------------------------------------------------------|
| SELx  | This read/write field is used to configure the MUX select for the peripheral trigger inputs. |

## Chapter 20

# External Watchdog Monitor (EWM)

### 20.1 Chip-specific EWM information

S32K14x has one instance of EWM. Products in the S32K11x series do not have EWM.

#### 20.1.1 EWM\_OUT signal configuration

EWM\_out signal shares its pad with other I/Os. To know the default state of that pad, see IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual.

#### 20.1.2 EWM Memory Map access

Only 8-bit access is supported.

#### 20.1.3 EWM low-power modes

This table shows the EWM low-power modes and the corresponding chip low-power modes.

Wait mode and power down mode is not supported. See [Module operation in available power modes](#) for details on available power modes.

### 20.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the RESET\_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM\_OUT\_b signal that when asserted resets or places an external circuit into a safe mode. The EWM\_OUT\_b signal is asserted upon the EWM counter time-out. An optional external input EWM\_in is provided to allow additional control of the assertion of EWM\_OUT\_b signal.

## 20.2.1 Features

Features of EWM module include:

- Independent LPO\_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO\_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of EWM\_OUT\_b.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 15 peripheral bus clock cycles.
- One output port, EWM\_OUT\_b, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM\_in, allows an external circuit to control the assertion of the EWM\_OUT\_b signal.

## 20.2.2 Modes of Operation

This section describes the module's operating modes.

### 20.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 15 peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

### 20.2.2.2 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 20.2.3 Block Diagram

This figure shows the EWM block diagram.

Figure 20-1. EWM Block Diagram

## 20.3 EWM Signal Descriptions

The EWM has two external signals, as shown in the following table.

### NOTE

All active-low signals are now represented with the suffix "\_b" throughout the chapter.

Table 20-1. EWM Signal Descriptions

| Signal    | Description                                                                                                                                                        | I/O |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| EWM_in    | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active low. | I   |
| EWM_OUT_b | EWM reset out signal                                                                                                                                               | O   |

## 20.4 Memory Map/Register Definition

This section contains the module memory map and registers.

### NOTE

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

### 20.4.1 EWM register descriptions

#### 20.4.1.1 EWM memory map

EWM base address: 4006\_1000h

| Offset | Register                                                | Width<br>(In bits) | Access     | Reset value |
|--------|---------------------------------------------------------|--------------------|------------|-------------|
| 0h     | <a href="#">Control Register (CTRL)</a>                 | 8                  | RW         | 00h         |
| 1h     | <a href="#">Service Register (SERV)</a>                 | 8                  | WORZ       | 00h         |
| 2h     | <a href="#">Compare Low Register (CMPL)</a>             | 8                  | RWONC<br>E | 00h         |
| 3h     | <a href="#">Compare High Register (CMPH)</a>            | 8                  | RWONC<br>E | FFh         |
| 5h     | <a href="#">Clock Prescaler Register (CLKPRESCALER)</a> | 8                  | RWONC<br>E | 00h         |

#### 20.4.1.2 Control Register (CTRL)

##### 20.4.1.2.1 Offset

| Register | Offset |
|----------|--------|
| CTRL     | 0h     |

##### 20.4.1.2.2 Function

The CTRL register is cleared by any reset.

**NOTE**

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

**20.4.1.2.3 Diagram****20.4.1.2.4 Fields**

| Field      | Function                                                                                                                                                                                                                                                                    |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-4<br>—   | Reserved                                                                                                                                                                                                                                                                    |
| 3<br>INTEN | Interrupt Enable.<br>This bit when set and EWM_OUT_b is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.                                                                                               |
| 2<br>INEN  | Input Enable.<br>This bit when set, enables the EWM_in port.                                                                                                                                                                                                                |
| 1<br>ASSIN | EWM_in's Assertion State Select.<br>Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one.                                                                                                |
| 0<br>EWMEN | EWM enable.<br>This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_OUT_b signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit. |

**20.4.1.3 Service Register (SERV)****20.4.1.3.1 Offset**

| Register | Offset |
|----------|--------|
| SERV     | 1h     |

### 20.4.1.3.2 Function

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

### 20.4.1.3.3 Diagram

### 20.4.1.3.4 Fields

| Field          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-0<br>SERVICE | <p>SERVICE</p> <p>The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true.</p> <ul style="list-style-type: none"> <li>The first or second data byte is not written correctly.</li> <li>The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <i>EWM_refresh_time</i>.</li> </ul> <p>15 peripheral bus clock cycles are required for <i>EWM_refresh_time</i></p> |

## 20.4.1.4 Compare Low Register (CMPL)

### 20.4.1.4.1 Offset

| Register | Offset |
|----------|--------|
| CMPL     | 2h     |

### 20.4.1.4.2 Function

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

**20.4.1.4.3 Diagram****20.4.1.4.4 Fields**

| Field    | Function                                                                                                                                                        |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-0      | COMPAREL                                                                                                                                                        |
| COMPAREL | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required. |

**20.4.1.5 Compare High Register (CMPH)****20.4.1.5.1 Offset**

| Register | Offset |
|----------|--------|
| CMPH     | 3h     |

**20.4.1.5.2 Function**

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

**NOTE**

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

**20.4.1.5.3 Diagram****20.4.1.5.4 Fields**

| Field    | Function                                                                                                                                                        |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-0      | COMPAREH                                                                                                                                                        |
| COMPAREH | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required. |

**20.4.1.6 Clock Prescaler Register (CLKPRESCALER)****20.4.1.6.1 Offset**

| Register     | Offset |
|--------------|--------|
| CLKPRESCALER | 5h     |

**20.4.1.6.2 Function**

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

**NOTE**

Write the required prescaler value before enabling the EWM.

**NOTE**

The implementation of this register is chip-specific. See the Chip Configuration details.

**20.4.1.6.3 Diagram**

**20.4.1.6.4 Fields**

| Field          | Function                                                                                                                                                                                                                         |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-0<br>CLK_DIV | CLK_DIV<br>Selected low power clock source for running the EWM counter can be prescaled as below. <ul style="list-style-type: none"><li>Prescaled clock frequency = low power clock source frequency / ( 1 + CLK_DIV )</li></ul> |

**20.5 Functional Description**

The following sections describe functional details of the EWM module.

**NOTE**

When the BUS\_CLK is lost, then EWM module doesn't generate the EWM\_OUT\_b signal and no refresh operation is possible

**20.5.1 The EWM\_OUT\_b Signal**

The EWM\_OUT\_b is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM\_OUT\_b could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM\_OUT\_b signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM\_OUT\_b signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM\_in pin is enabled and EWM\_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM\_OUT\_b pin)

The EWM\_OUT\_b is asserted after any reset by the virtue of the external pull-down mechanism on the EWM\_OUT\_b signal. Then, to deassert the EWM\_OUT\_b signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM\_OUT\_b signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM\_OUT\_b signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

### Note

EWM\_OUT\_b pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

## 20.5.2 EWM\_OUT\_b pin state in low power modes

During Wait, Stop, and Power Down modes the EWM\_OUT\_b pin preserve its state before entering Wait or Stop mode. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

## 20.5.3 The EWM\_in Signal

The EWM\_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM\_OUT\_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM\_OUT\_b signal that controls the gating circuit.

The EWM\_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM\_in functionality (setting the CTRL[INEN] bit), the EWM\_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM\_OUT\_b stays in the deasserted state; otherwise, the EWM\_OUT\_b output signal is asserted.

### **Note**

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM\_in pin is deasserted.

## **20.5.4 EWM Counter**

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

## **20.5.5 EWM Compare Registers**

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM\_OUT\_b is asserted.

## **20.5.6 EWM Refresh Mechanism**

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

**Table 20-2. EWM Refresh Mechanisms**

| Condition                                                             | Mechanism                                                                                                                                                                                                             |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An EWM refresh action completes when:<br>$CMPL < Counter < CMPH$ .    | The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_b output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state.. |
| An EWM refresh action completes when<br>$Counter < CMPL$              | The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.                                      |
| Counter value reaches CMPH prior to completion of EWM refresh action. | Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal.                                                             |

### 20.5.7 EWM Interrupt

When EWM\_OUT\_b is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect EWM\_OUT\_b. The EWM\_OUT\_b signal can be deasserted only by forcing a system reset.

### 20.5.8 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK\_DIV]. This divided clock is used to run the EWM counter.

#### NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

# Chapter 21

## Error Injection Module (EIM)

### 21.1 Chip-specific EIM information

S32K1xx and S32K14xW has one instance of the EIM.

#### 21.1.1 EIM channel assignments

Each EIM channel corresponds to a specific RAM array target. The EIM channel can inject errors on accesses to that specific RAM array. The following table shows the channel assignments.

**Table 21-1. RAM array targets of EIM channels**

| EIM channel | RAM array target |          |          |
|-------------|------------------|----------|----------|
|             | S32K14x          | S32K14xW | S32K11x  |
| 0           | SRAM_L           | SRAM_L   | SRAM_U   |
| 1           | SRAM_U           | SRAM_U   | Reserved |

### 21.2 Introduction

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

## 21.2.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the Single Error Correct – Dual Error Detect (SEC-DED) ECC function of the related system.

### NOTE

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

Figure 21-1. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

## 21.2.2 Features

The EIM includes these features:

- Supports 2 error injection channels
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

## 21.3 EIM register descriptions

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

### Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

### Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.
  - The first word, Word0 (EICHD $n$ \_WORD0), defines the checkbit mask. See [Error Injection Channel Descriptor  \$n\$ , Word0](#) for details.
  - The remaining words, Word1-3 (EICHD $n$ \_WORD1-3), define the data mask. Word2 and Word3 are used only when required by the total width of the

channel's data mask. See Error injection channel descriptor: DATA\_MASK details and the individual registers' descriptions.

The multiple channel descriptors are organized sequentially.

### Error injection channel descriptor: DATA\_MASK details

For each channel: The following table shows the total width of DATA\_MASK and the distribution of its bits across the WORD registers.

| Channel | DATA_MASK total width (bits) | Specific bits of DATA_MASK in |       |       |
|---------|------------------------------|-------------------------------|-------|-------|
|         |                              | WORD1                         | WORD2 | WORD3 |
| 0       | 32                           | 31-0                          | —     | —     |

## 21.3.2 Error Injection Module Configuration Register (EIMCR)

### 21.3.2.1 Offset

| Register | Offset |
|----------|--------|
| EIMCR    | 0h     |

### 21.3.2.2 Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

### 21.3.2.3 Diagram

### 21.3.2.4 Fields

| Field      | Function                                                                                                                                                                                      |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1<br>—  | Reserved                                                                                                                                                                                      |
| 0<br>GEIEN | Global Error Injection Enable<br>This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset.<br>0b - Disabled<br>1b - Enabled |

## 21.3.3 Error Injection Channel Enable register (EICHEN)

### 21.3.3.1 Offset

| Register | Offset |
|----------|--------|
| EICHEN   | 4h     |

### 21.3.3.2 Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

#### NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

### 21.3.4 Error Injection Channel Descriptor n, Word0 (EICHD0\_WORD0 - EICHD1\_WORD0)

#### 21.3.4.1 Offset

| Register     | Offset |
|--------------|--------|
| EICHD0_WORD0 | 100h   |
| EICHD1_WORD0 | 200h   |

### 21.3.4.2 Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT\_MASK. Each bit of CHKBIT\_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH $n$ EN].

## 21.3.5 Error Injection Channel Descriptor n, Word1 (EICHD0\_WORD1 - EICHD1\_WORD1)

### 21.3.5.1 Offset

| Register     | Offset |
|--------------|--------|
| EICHD0_WORD1 | 104h   |
| EICHD1_WORD1 | 204h   |

### 21.3.5.2 Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0\_3DATA\_MASK correspond to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH $n$ EN].

### 21.3.5.3 Diagram

### 21.3.5.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0          | Data Mask Bytes 0-3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| B0_3DATA_MASK | <p>This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified.</p> <p><b>NOTE:</b> For each channel: For the exact width of B0_3DATA_MASK and the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, see Error injection channel descriptor: DATA_MASK details.</p> <p>0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified.<br/>1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.</p> |

## 21.4 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH $n$ EN] field, where  $n$  denotes the channel number.
- Write 1 to EIMCR[GEIEN].

### NOTE

When the use case for a channel requires writing any EICH $Dn$ \_WORD register, write the EICH $Dn$ \_WORD register before executing the two-stage enablement mechanism. A successful write to any EICH $Dn$ \_WORD register clears the corresponding EICHEN[EICH $n$ EN] field.

The EIM supports 2 error injection channels. Each channel:

- Is assigned to a single memory array interface.
- Intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICH $Dn$ \_WORD register defines which bit of the read data and/or checkbit bus to invert.

Figure 21-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

### 21.4.1 Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT\_MASK or DATA\_MASK in the EICHD<sub>n</sub>\_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT\_MASK or DATA\_MASK in the EICHD<sub>n</sub>\_WORD registers.

#### NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

See below pseudocode:

- Program the one to two bits of the data bus to invert (EICHD<sub>x</sub>\_WORD<sub>y</sub>)
- Enable the channel to allow data inversions (EICH<sub>x</sub>EN)
- Enable the EIM module global enable to start error injections (EIMCR)
- Read from the memory being injected to see the error
- Read from the memory being injected to see the error
- In the error handling routine
- Turn off the EIM global module enable (EIMCR)
- Disable the EIM channel (EICH<sub>x</sub>EN)
- Clear the data inversion register (EICHD<sub>x</sub>\_WORD<sub>y</sub>)

# Chapter 22

## Error Reporting Module (ERM)

### 22.1 Chip-specific ERM information

S32K1xx and S32K14xW has one instance of the ERM.

#### 22.1.1 Sources of memory error events

Each ERM channel *n* corresponds to a source of potential memory error events. The following table shows the channel assignments.

**Table 22-1. Memory error event sources for ERM channels**

| ERM channel <i>n</i> | Memory <i>n</i> event source <sup>1</sup> |          |          |
|----------------------|-------------------------------------------|----------|----------|
|                      | S32K14x                                   | S32K14xW | S32K11x  |
| 0                    | SRAM_L                                    | SRAM_L   | SRAM_U   |
| 1                    | SRAM_U                                    | SRAM_U   | Reserved |

1. Throughout this chapter, "Memory *n*" designates the memory array sourced by ERM channel *n*.

### 22.2 Introduction

#### 22.2.1 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with Error Correction Code (ECC). The ERM collects ECC events on memory accesses for platform local memory arrays, such as flash memory, system RAM, or peripheral RAMs. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments.

## 22.2.2 Features

The ERM includes these features:

- Capturing of address information on single-bit correction and non-correctable ECC events
- Optional interrupt notification on captured ECC events
- Support for ECC event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel

## 22.3 ERM register descriptions

The ERM provides an IPS programming model mapped to an on-platform peripheral slot.

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes

Attempted accesses to undefined (reserved) memory regions can result in undefined behavior.

Attempted updates to the programming model when the ERM is in the middle of an operation result in non-deterministic behavior.

### 22.3.1 ERM memory map

ERM base address: 4001\_8000h

| Offset | Register                                           | Width<br>(In bits) | Access | Reset value |
|--------|----------------------------------------------------|--------------------|--------|-------------|
| 0h     | <a href="#">ERM Configuration Register 0 (CR0)</a> | 32                 | RW     | 0000_0000h  |
| 10h    | <a href="#">ERM Status Register 0 (SR0)</a>        | 32                 | W1C    | 0000_0000h  |

*Table continues on the next page...*

| Offset | Register                                   | Width<br>(In bits) | Access | Reset value |
|--------|--------------------------------------------|--------------------|--------|-------------|
| 100h   | ERM Memory n Error Address Register (EAR0) | 32                 | RO     | 0000_0000h  |
| 110h   | ERM Memory n Error Address Register (EAR1) | 32                 | RO     | 0000_0000h  |

## 22.3.2 ERM Configuration Register 0 (CR0)

### 22.3.2.1 Offset

| Register | Offset |
|----------|--------|
| CR0      | 0h     |

### 22.3.2.2 Function

This 32-bit control register configures the interrupt notification capability for:

- Channel 0
- Channel 1

## 22.3.4 ERM Memory n Error Address Register (EAR0 - EAR1)

### 22.3.4.1 Offset

| Register | Offset |
|----------|--------|
| EAR0     | 100h   |
| EAR1     | 110h   |

### 22.3.4.2 Function

Each ERM Memory  $n$  Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory  $n$ , where  $n$  denotes the memory channel. Any attempted write to  $\text{EAR}_n$  is ignored.

## 22.4 Functional description

### 22.4.1 Single-bit correction events

When a single-bit correction event on Memory  $n$  is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit  $SRx[SBCn]$  to 1.
- Records the corresponding access address that initiated the event in the Memory  $n$  Error Address Register:  $EARn$  (if this register is present for the channel).

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to  $SRx[SBCn]$  to change its value to 0.

### 22.4.1.1 Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. This sequence describes how to use the option:

1. To enable interrupt notification for single-bit correction events on Memory  $n$ , set  $CRx[ESCIEn]$  to 1.
2. Subsequently, when a single-bit correction event on Memory  $n$  is detected, the ERM:
  - Records the event and address, as usual.
  - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to  $SRx[SBCn]$  to change its value to 0.

### 22.4.2 Non-correctable error events

When a non-correctable ECC error event on Memory  $n$  is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit:  $SRx[NCEn]$  to 1.
- Records the corresponding access address that initiated the event in the Memory  $n$  Error Address Register:  $EARn$  (if this register is present for the channel).

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to  $SRx[NCEn]$  to change its value to 0.

### 22.4.2.1 Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. This sequence describes how to use the option:

1. To enable interrupt notifications for non-correctable error events on Memory  $n$ , set  $CRx[ENCIE_n]$  to 1.
2. Subsequently, when a non-correctable error event on Memory  $n$  is detected, the ERM:
  - Records the event and address as usual.
  - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to  $SRx[NCE_n]$  to change its value to 0.

## 22.5 Initialization

For each ERM channel, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding  $SRx[SBC_n]$  or  $SRx[NCE_n]$  field that stores the record of the event.
3. Program the applicable  $CRx[ESCIEn]$  and  $CRx[ENCIE_n]$  fields to enable ERM interrupts as desired.

## Chapter 23

# Watchdog timer (WDOG)

## 23.1 Chip-specific WDOG information

### 23.1.1 WDOG clocks

The WDOG module has following selectable clock sources:

- Internal low power oscillator (LPO\_CLK)
- Internal Slow IRC clock (SIRC)
- System oscillator clock (SOSC)
- Bus clock

#### NOTE

- For safety applications, WDOG should run on a different clock than CMU.
- WDOG\_CNT reset read value can vary depending on timestamp, since it is a default running counter.

### 23.1.2 WDOG low-power modes

This table shows the WDOG low-power modes and the corresponding chip low-power modes.

Wait mode is not supported in this device. See [Module operation in available power modes](#) for details on available power modes.

### 23.1.3 Default watchdog timeout

The timeout depends on the watchdog counter clock source. Following initial power on the watchdog is clocked by the LPO128K\_CLK and will issue a timeout after 1024 cycles. This results in the Watchdog timeout being generated after approximately 8 ms, which will force a MCU reset. To avoid this condition, please ensure that the watchdog is configured or refreshed before the 1024 cycles have elapsed.

### 23.1.4 Watchdog Timeout Reaction

The WDOG timeout reaction is by default configured to generate a system reset. It can be alternatively configured for an interrupt reaction followed by a reset event by appropriately configuring WDOG and RCM. When configured as an interrupt, the reset event will be raised by WDOG after some delay (delay configurable within RCM and fixed within WDOG).

The WDG feature is controlled by WDOG.CS whereas RGM feature is controlled by RCM.SRIE. The delay durations are different. For WDOG it is fixed 128 bus clock cycles. For RCM, it is configurable. The RCM IRQ is enabled when both SRIE[WDOG] and SRIE[GIE] are set.

Following table explains the behavior w.r.t. different configurations.

| WDOG.CS[INT] | RCM.SRIE[WDOG] | RCM.SRIE[GIE] | Behavior                                                       |
|--------------|----------------|---------------|----------------------------------------------------------------|
| 0            | 0              | 0             | WDOG reset.                                                    |
| 0            | 0              | 1             | WDOG reset.                                                    |
| 0            | 1              | 0             | No IRQ. RCM delayed WDOG reset.                                |
| 0            | 1              | 1             | RCM IRQ. RCM delayed WDOG reset.                               |
| 1            | 0              | 0             | WDOG IRQ. WDOG delayed WDOG reset.                             |
| 1            | 0              | 1             | WDOG IRQ. WDOG delayed WDOG reset.                             |
| 1            | 1              | 0             | WDOG IRQ. WDOG delayed + RCM delayed WDOG reset.               |
| 1            | 1              | 1             | WDOG IRQ <sup>1</sup> . WDOG delayed + RCM delayed WDOG reset. |

1. WDOG IRQ will be executed and RCM IRQ will be pending based on the fact that WDOG has lower number.

## 23.2 Introduction

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

### 23.2.1 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequence for counter refresh
  - Refresh sequence of writing 0xA602 and then 0xB480
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset.
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
  - Forced reset occurs 128 bus clocks after the interrupt vector fetch.
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.
- Robust write sequence for unlocking write-once configuration bits

- Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
- Software must make updates within 128 bus clocks after unlocking and before WDOG closing unlock window.

## 23.2.2 Block diagram

The following figure shows a block diagram of the WDOG module.

Figure 23-1. WDOG block diagram

## 23.3 Memory map and register definition

### 23.3.1 WDOG register descriptions

#### 23.3.1.1 WDOG memory map

WDOG base address: 4005\_2000h

| Offset | Register                                                  | Width<br>(In bits) | Access | Reset value |
|--------|-----------------------------------------------------------|--------------------|--------|-------------|
| 0h     | <a href="#">Watchdog Control and Status Register (CS)</a> | 32                 | RW     | 0000_2980h  |
| 4h     | <a href="#">Watchdog Counter Register (CNT)</a>           | 32                 | RW     | 0000_0000h  |
| 8h     | <a href="#">Watchdog Timeout Value Register (TOVAL)</a>   | 32                 | RW     | 0000_0400h  |
| Ch     | <a href="#">Watchdog Window Register (WIN)</a>            | 32                 | RW     | 0000_0000h  |

## 23.3.1.2 Watchdog Control and Status Register (CS)

### 23.3.1.2.1 Offset

| Register | Offset |
|----------|--------|
| CS       | 0h     |

### 23.3.1.2.2 Function

This section describes the function of Watchdog Control and Status Register.

#### NOTE

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

### 23.3.1.2.3 Diagram

### 23.3.1.2.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 0<br>STOP   | <p>Stop Enable</p> <p>This write-once bit enables the watchdog to operate when the chip is in stop mode.</p> <p>0b - Watchdog disabled in chip stop mode.</p> <p>1b - Watchdog enabled in chip stop mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 23.3.1.3 Watchdog Counter Register (CNT)

#### 23.3.1.3.1 Offset

| Register | Offset |
|----------|--------|
| CNT      | 4h     |

#### 23.3.1.3.2 Function

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

### NOTE

All other writes to this register are illegal and force a reset.

#### 23.3.1.3.3 Diagram

#### 23.3.1.3.4 Fields

| Field           | Function                          |
|-----------------|-----------------------------------|
| 31-16<br>—      | Reserved                          |
| 15-8<br>CNTHIGH | High byte of the Watchdog Counter |
| 7-0<br>CNTLOW   | Low byte of the Watchdog Counter  |

#### 23.3.1.4 Watchdog Timeout Value Register (TOVAL)

### 23.3.1.4.1 Offset

| Register | Offset |
|----------|--------|
| TOVAL    | 8h     |

### 23.3.1.4.2 Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

#### NOTE

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

### 23.3.1.4.3 Diagram

### 23.3.1.4.4 Fields

| Field             | Function                       |
|-------------------|--------------------------------|
| 31-16<br>—        | Reserved                       |
| 15-8<br>TOVALHIGH | High byte of the timeout value |
| 7-0<br>TOVALLOW   | Low byte of the timeout value  |

## 23.3.1.5 Watchdog Window Register (WIN)

### 23.3.1.5.1 Offset

| Register | Offset |
|----------|--------|
| WIN      | Ch     |

### 23.3.1.5.2 Function

This section describes the watchdog window register. When window mode is enabled (CS[WIN] is set), The WIN register determines the earliest time that a refresh sequence is considered valid. See the [Watchdog refresh mechanism](#) section.

The WIN register value must be less than the TOVAL register value.

### 23.3.1.5.3 Diagram

| 7-0<br>WINLOW   | Low byte of Watchdog Window  |

## 23.4 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

### 23.4.1 Clock source

The watchdog counter has the clock source options selected by programming CS[CLK]. See the "chip-specific information" section for available clock inputs and the default option for this device.

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see [Backup reset](#).

#### NOTE

The *default* clock source of WDOG should be enabled after its functional reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

**Table 23-1. Watchdog timeout availability**

| Reference clock | Prescaler    | Watchdog time-out availability  |
|-----------------|--------------|---------------------------------|
| REF_CLK         | Pass through | 1×RCP to 65535×RCP <sup>1</sup> |
|                 | Enable       | 256×RCP to 16776960×RCP         |

1. RCP means Reference Clock Period.

#### NOTE

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5

periods of the new clock source after the configuration time period ( 128 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

### 23.4.2 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

Figure 23-2. Refresh opportunity for the Watchdog counter

### 23.4.2.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

### 23.4.2.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes ( 0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80) if WDOG\_CS[CMD32EN] is 0;
- one 32-bit write (0xB480\_A602) if WDOG\_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

#### Note

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

## 23.4.3 Configuring the Watchdog

### 23.4.3.1 Configuring the Watchdog Once

**All watchdog control bits, timeout value, and window value are write-once after reset . This means that after a write has occurred they cannot be changed unless a reset occurs.** This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

### 23.4.3.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

#### 23.4.3.2.1 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 within 16 bus clocks at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 128 bus clocks; otherwise, the watchdog closes the unlock window.

#### NOTE

Due to the 128 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

The example codes can be found at end of this chapter.

### 23.4.4 Using interrupts to delay resets

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay the forcing a reset.

### 23.4.5 Backup reset

#### NOTE

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

### 23.4.6 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode,** set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode,** set CS[WAIT].
- **For Stop mode,** set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

#### NOTE

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

### **23.4.7 Fast testing of the watchdog**

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

#### **23.4.7.1 Testing each byte of the counter**

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)

6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

### NOTE

CS[TST] is cleared by a POR only and not affected by other resets.

## 23.4.7.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

## 23.5 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

### NOTE

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

### NOTE

When Chip startup from BOOT ROM then jump to flash, the watchdog would be disabled in the beginning of bootloader, and enabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG\_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

## 23.5.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG\_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

## 23.5.2 Disable Watchdog after Reset

All of watchdog registers are unlocked by reset. Therefore, unlock sequence is unnecessary, but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]); // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

## 23.5.3 Configure Watchdog

The watchdog can be configured once by set the WDOG\_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG\_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

### *Configure once*

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0); //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
           WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

### *Configure for reconfigurable*

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0); //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
```

```
        WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);  
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect  
EnableInterrupts; //enable global interrupt
```

## 23.5.4 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt  
WDOG_CNT = 0xB480A602; // refresh watchdog  
EnableInterrupts; // enable global interrupt
```

# Chapter 24

## Cyclic Redundancy Check (CRC)

### 24.1 Chip-specific CRC information

#### NOTE

All input bytes need to be byte transposed. Any additional transpose will be governed by the CRC protocol requirement.

### 24.2 Introduction

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

#### 24.2.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or byte-wise. This option is required for certain CRC standards. A byte-wise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the byte-wise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

### 24.2.2 Block diagram

The following is a block diagram of the CRC.

**Figure 24-1. Programmable cyclic redundancy check (CRC) block diagram**

### 24.2.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

### 24.2.3.1 Run mode

This is the basic mode of operation.

### 24.2.3.2 Low-power modes (Stop)

Any CRC calculation in progress stops when the device enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the device.

## 24.3 Memory map and register descriptions

## NOTE

Write access to the register addresses not mapped to the peripheral but included in the address space of the peripheral

may result in unpredictable functionality. The CRC module should be reconfigured if a transfer error occurs

## 24.3.1 CRC register descriptions

### 24.3.1.1 CRC Memory map

CRC base address: 4003\_2000h

| Offset | Register                                        | Width<br>(In bits) | Access | Reset value |
|--------|-------------------------------------------------|--------------------|--------|-------------|
| 0h     | <a href="#">CRC Data register (DATA)</a>        | 32                 | RW     | FFFF_FFFFh  |
| 4h     | <a href="#">CRC Polynomial register (GPOLY)</a> | 32                 | RW     | 0000_1021h  |
| 8h     | <a href="#">CRC Control register (CTRL)</a>     | 32                 | RW     | 0000_0000h  |

### 24.3.1.2 CRC Data register (DATA)

#### 24.3.1.2.1 Offset

| Register | Offset |
|----------|--------|
| DATA     | 0h     |

#### 24.3.1.2.2 Function

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

### 24.3.1.2.3 Diagram

### 24.3.1.2.4 Fields

| Field       | Function                                                                                                                                                                                                                                                                                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>HU | CRC High Upper Byte<br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 23-16<br>HL | CRC High Lower Byte<br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 15-8<br>LU  | CRC Low Upper Byte<br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.                                                                                                                                                                      |
| 7-0<br>LL   | CRC Low Lower Byte<br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.                                                                                                                                                                      |

### 24.3.1.3 CRC Polynomial register (GPOLY)

### 24.3.1.3.1 Offset

| Register | Offset |
|----------|--------|
| GPOLY    | 4h     |

### 24.3.1.3.2 Function

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

### 24.3.1.3.3 Diagram

### 24.3.1.3.4 Fields

| Field         | Function                                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>HIGH | High Polynomial Half-word<br>Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0). |
| 15-0<br>LOW   | Low Polynomial Half-word<br>Writable and readable in both 32-bit and 16-bit CRC modes.                                                                    |

## 24.3.1.4 CRC Control register (CTRL)

### 24.3.1.4.1 Offset

| Register | Offset |
|----------|--------|
| CTRL     | 8h     |

### 24.3.1.4.2 Function

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

### 24.3.1.4.3 Diagram

### 24.3.1.4.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 24.4 Functional description

### 24.4.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC\_CTRL[WAS], CRC\_GPOLY, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC\_CTRL[WAS] enables the programming of the seed value into the CRC\_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC\_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

### 24.4.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

#### 24.4.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC\_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 16-bit polynomial to the CRC\_GPOLY[LOW] field. The CRC\_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC\_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC\_DATA[LU:LL]. CRC\_DATA[HU:HL] are not used.
6. Clear CRC\_CTRL[WAS] to start writing data values.
7. Write data values into CRC\_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC\_DATA[LU:LL].

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

#### 24.4.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC\_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 32-bit polynomial to CRC\_GPOLY[HIGH:LOW].
4. Set CRC\_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC\_DATA[HU:HL:LU:LL].
6. Clear CRC\_CTRL[WAS] to start writing data values.
7. Write data values into CRC\_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC\_DATA[HU:HL:LU:LL]. The CRC is calculated byte-wise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

### 24.4.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

#### 24.4.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00.

No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

Bits in a byte are transposed, while bytes are not transposed.

reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

**Figure 24-2. Transpose type 01**

3. CTRL[TOT] or CTRL[TOTR] is 10.

Both bits in bytes and bytes are transposed.

reg[31:0] becomes = {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}

**Figure 24-3. Transpose type 10**

4. CTRL[TOT] or CTRL[TOTR] is 11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

**Figure 24-4. Transpose type 11**

### NOTE

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[**HU**:**HL**] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

## 24.4.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

## 24.5 Use cases

### NOTE

The following tables apply to little-endian format.

### 24.5.1 CRC Control Register programming

The following table shows the CRC Control Register programming for 16-bit CRC.

**Table 24-1. Control Register (CTRL) programming for 16-bit CRC**

| Algorithm              | Poly   | Seed   | Ref In | Ref Out | XOR Out | CTRL[TOT] | CTRL[TOTR] | CTRL[FXOR] |
|------------------------|--------|--------|--------|---------|---------|-----------|------------|------------|

| CRC16_MAXIM        | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_MCRF4XX      | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_RIELLO       | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_T10_DIF      | [ 31 : 16 ] = Unknown [ 15 : 0 ] = Valid Data |
| CRC16_TELEDISK     | [ 31 : 16 ] = Unknown [ 15 : 0 ] = Valid Data |
| CRC16_TMS37157     | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_USB          | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_A            | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_KERMIT       | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_MODBUS       | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_X_25         | [ 31 : 16 ] = Valid Data [ 15 : 0 ] = Unknown |
| CRC16_XMODEM       | [ 31 : 16 ] = Unknown [ 15 : 0 ] = Valid Data |

The following table shows the expected read data fields for 32-bit CRC.

**Table 24-4. Expected read data fields for 32-bit CRC**

| Algorithm     | CRC DATA Register (DATA) |
|---------------|--------------------------|
| CRC - 32      | [ 31 : 0 ] = Valid Data  |
| CRC-32/BZIP2  | [ 31 : 0 ] = Valid Data  |
| CRC-32C       | [ 31 : 0 ] = Valid Data  |
| CRC-32D       | [ 31 : 0 ] = Valid Data  |
| CRC-32/MPEG-2 | [ 31 : 0 ] = Valid Data  |
| CRC-32/POSIX  | [ 31 : 0 ] = Valid Data  |
| CRC-32Q       | [ 31 : 0 ] = Valid Data  |
| CRC-32/JAMCRC | [ 31 : 0 ] = Valid Data  |
| CRC-32/XFER   | [ 31 : 0 ] = Valid Data  |

# Chapter 25

## Reset and Boot

### 25.1 Introduction

This table shows the reset sources that are supported.

Table 25-1. Reset sources

| Reset sources | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 25.2 Reset

This section discusses basic reset mechanisms and sources. Some peripheral modules that cause resets can be configured to cause interrupts instead. See the individual module chapters for more information.

Each reset source has an associated field in the Reset Control Module (RCM) [System Reset Status \(RCM\\_SRS\)](#) register. Besides immediate system reset, the RCM also supports optional configurable delayed system reset while an interrupt is generated. This provides software an option to perform a graceful shutdown.

The MCU exits reset in RUN mode where the CPU is executing code. See [Boot](#) for more details.

### 25.2.1 Power-on reset (POR)

When power is initially applied to the MCU or when the supply voltage drops below the POR detect voltage ( $V_{POR}$ ), the POR circuit causes a POR reset condition.

As the supply voltage rises, the LVD circuit holds the MCU in reset until the supply has risen above the LVD low voltage detect threshold ( $V_{LVD}$ ). Following a POR, the MCU writes 1 to the POR and LVD fields in [RCM\\_SRS](#) register.

Out of POR, both `RCM_SRS[POR]` and `RCM_SRS[LVD]` are configured as 1 by MCU.

While normal operation, if device supply goes below  $V_{POR}$ , MCU writes 1 to both `RCM_SRS[POR]` and `RCM_SRS[LVD]`. While normal operation, if device supply goes below  $V_{LVD}$  (provided LVD is enabled to generate a reset) or  $V_{LVR}$  but above  $V_{POR}$ , MCU writes 1 to `RCM_SRS[LVD]`.

### 25.2.2 System reset sources

Resetting the MCU provides a way to start processing from a known set of initial conditions. System reset begins with the on-chip regulator in full regulation and system clocking generation from an internal reference. When the processor exits reset, it:

- Reads the start stack pointer (SP) (`SP_main`) from vector-table offset 0
- Reads the start program counter (PC) from vector-table offset 4
- Writes `0xFFFF_FFFF` to the Link Register (LR)

The on-chip peripheral modules are disabled and the non-analog I/O pins are initially configured as disabled. The pins with analog functions assigned to them are configured for their analog functions after reset.

During and following a reset, the JTAG pins have their associated input pins configured as:

- TDI as pullup (PU)
- TCK as pulldown (PD)
- TMS as pullup

and associated output pin configured as:

- TDO with no pull-down or pull-up

### 25.2.2.1 External pin reset

RESET\_B is a shared pin (See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual). The user must configure the corresponding [PORT\\_PCR](#) register prior to using this pin as RESET\_B. On any reset event, the MCU configures the corresponding pad as RESET\_B pad. Asserting RESET\_B wakes the MCU from any mode. The system clock is required to be available for proper functionality of Reset Pin. During a pin reset, the MCU writes 1 to [RCM\\_SRS\[PIN\]](#).

#### 25.2.2.1.1 RESET\_B pin filter

The RESET\_B pin filter supports filtering from both the 128 kHz LPO clock and the bus clock. [RCM\\_RPC\[RSTFLTSS\]](#), [RCM\\_RPC\[RSTFLTSRW\]](#), and [RCM\\_RPC\[RSTFLTSEL\]](#) control this functionality. The filters are asynchronously reset on chip POR. The reset value for each filter assumes the RESET\_B pin is negated.

For all stop modes where LPO clock is still active, the only filtering option is the LPO clock filter. The filtering logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected as described in [RCM\\_RPC](#) register.

The LPO filter has a fixed filter value. The pulses upto 2 LPO128K\_CLK cycles will always be filtered. The pulses longer than 3 LPO128K\_CLK cycles will always get passed and generate a RESET. The pulses in between 2 to 3 LPO128K\_CLK cycles may or may not generate reset based on reset alignment with clock edge.

### 25.2.2.2 Low voltage detect (LVD)

The chip includes a system for managing low voltage conditions to protect memory contents and control MCU system states during supply voltage variations. The system consists of a POR circuit and an LVD circuit. The LVD system is always enabled in HSRUN and Normal Run. The LVD system is disabled when entering VLPx modes.

The LVD system can be configured to generate a reset upon detection of a low voltage condition by writing 1 to [PMC\\_LVDSC1\[LVDRE\]](#). After an LVD reset has occurred, the LVD system holds the MCU in reset until the supply voltage has risen above the low voltage detection threshold. The MCU writes 1 to [RCM\\_SRS\[LVD\]](#) bit is set following either an LVD reset or POR.

Besides LVD operation, the device also supports LVR(Low Voltage Reset) operation. If the supply voltage falls below the reset trip point (VLVR), a system reset will be generated. LVR system is enabled in all modes. LVDRE has effect on LVD operation only.

Out of POR, both RCM\_SRS[POR] and RCM\_SRS[LVD] are configured as 1 by MCU.

While normal operation, if device supply goes below VPOR, MCU writes 1 to both RCM\_SRS[POR] and RCM\_SRS[LVD]. While normal operation, if device supply goes below VLVD (provided LVD is enabled to generate a reset) or VLVR but above VPOR, MCU writes 1 to RCM\_SRS[LVD].

### 25.2.2.3 Watchdog reset

Watchdog timer (WDOG) monitors the operation of the system by expecting periodic communication from the software. This communication is generally known as servicing or refreshing the watchdog. If this periodic refreshing does not occur, the watchdog issues a system reset. The watchdog reset causes the MCU to write 1 to [RCM\\_SRS\[WDOG\]](#).

### 25.2.2.4 Loss-of-clock (LOC) reset

LOC reset is enabled when SOSC clock monitor is enabled (by writing 1 to [SOSCCM](#)) and configured to generate a reset on error (by writing 1 to [SOSCCMRE](#)). If the error bit ([SOSCERR](#)) is written to 1 and LOC reset is enabled (as mentioned above), the MCU resets. The MCU writes 1 to the [LOC](#) field to indicate this reset source.

#### NOTE

To prevent unexpected loss of clock reset events, all clock monitors should be disabled before entering any low power modes, including VLPR.

### 25.2.2.5 Loss-of-lock (LOL) reset

LOL reset is enabled when PLL clock monitor is enabled (by writing 1 to [SCG\\_SPLLCSR\[SPLLCM\]](#)) and configured to generate a reset on error (by writing 1 to [SCG\\_SPLLCSR\[SPLLCMRE\]](#)). If the error bit ([SCG\\_SPLLCSR\[SPLLERR\]](#)) is written to 1 and LOL reset is enabled (as mentioned above), the MCU resets. The MCU writes 1 to [RCM\\_SRS\[LOL\]](#) field is set to indicate this reset source.

#### NOTE

This reset source does not cause a reset if the chip is in any Stop mode.

SPLL also flags LOL in case if the reference to SPLL goes faulty. So while using SPLL, any failure in reference clock source, i.e., SOSC might lead to either LOC or LOL event.

### 25.2.2.6 Stop mode acknowledge error (SACKERR)

The Stop mode acknowledge error (SACKERR) reset is generated if the core attempts to enter Stop mode, but not all modules acknowledge stop mode within  $(2^{16} + 1)$  (corresponding to 0.5s)) cycles of the LPO128K\_CLK.

A module might not acknowledge the entry to Stop mode if an error condition occurs. The error can be caused by a failure of an external clock input to a module.

The [RCM\\_SRS\[SACKERR\]](#) bit is written to 1 to indicate this reset source.

### 25.2.2.7 Software reset (SW)

The SYSRESETREQ bit in the NVIC application interrupt and reset control register can be written to 1 to force a software reset. (See [Arm's NVIC](#) documentation for the full description of the register fields, especially the VECTKEY field requirements.) Writing 1 to SYSRESETREQ generates a software reset request. This reset forces a system reset of all major components except for the debug module. A software reset causes the MCU to write 1 to [RCM\\_SRS\[SW\]](#) field.

### 25.2.2.8 Lockup reset (LOCKUP)

The LOCKUP gives immediate indication of seriously errant kernel software. This is the result of the core being locked because of an unrecoverable exception following the activation of the processor's built in system state protection hardware.

The LOCKUP condition causes a system reset and also causes the MCU to write 1 to [RCM\\_SRS\[LOCKUP\]](#) field. See [Arm Cortex-M4 Devices Generic User Guide](#) (for S32K14x devices) and [Arm Cortex-M0 Devices Generic User Guide](#) (for S32K11x devices) for details on 'lockup' event.

### 25.2.2.9 MDM-AP system reset request

Writing 1 to the system reset request field in the [MDM-AP control register](#) initiates a system reset. This is the primary method for resets via the JTAG/SWD interface. The system reset is held until this field is written to 0.

Writing 1 to the core hold reset bit in the [MDM-AP control register](#) holds the core in reset as the rest of the chip comes out of system reset.

### 25.2.3 MCU Resets

A variety of resets are generated by the MCU to reset different modules.

#### 25.2.3.1 POR Only

The POR Only reset asserts on the POR reset source only. It resets the PMC registers.

The POR Only reset also causes all other reset types to occur.

#### 25.2.3.2 Chip POR

The Chip POR asserts on POR, LVR or LVD.

The Chip POR also causes the chip reset (including early chip reset) to occur.

#### 25.2.3.3 Early chip reset

The early chip reset asserts on all reset sources. It resets only the flash memory module. It deasserts before flash memory initialization begins (earlier than the chip reset deassertion).

#### 25.2.3.4 Chip reset

Chip reset asserts on all reset sources and only deasserts after flash memory initialization has completed and the RESET\_B pin has also negated.

#### 25.2.3.5 Core reset

The core comes out of reset after one cycle of chip reset. The core can be held in reset using the core hold reset bit in the MDM-AP control register as the rest of the chip comes out of system reset.

## 25.2.4 Reset pin

For all reset sources, the RESET\_B pin is driven low by the MCU for at least 128 bus clock cycles and until flash memory initialization has completed.

After flash memory initialization has completed, the RESET\_B pin is released and the internal chip reset deasserts. Keeping the RESET\_B pin asserted externally delays the negation of the internal chip reset.

## 25.2.5 Debug resets

The following sections detail the debug resets.

### 25.2.5.1 JTAG reset

The JTAG module generate a system reset when certain IR codes are selected. This functional reset is asserted when EXTEST, HIGHZ and CLAMP instructions are active. The reset source from the JTAG module is released when any other IR code is selected. A JTAG reset causes the MCU to write 1 to [RCM\\_SRS\[JTAG\]](#) field.

### 25.2.5.2 Resetting the debug subsystem

Use the CDBGIRSTREQ field within the SWJ-DP CTRL/STAT register to reset the debug modules. However the CDBGIRSTREQ field does not reset all debug-related registers.

CDBGIRSTREQ resets only the debug-related registers within the following modules:

- SWJ-DP
- AHB-AP
- TPIU
- MDM-AP (MDM control and status registers)

CDBGIRSTREQ does not reset the debug-related registers within these modules:

- CM4 core (core debug registers: DHCSR, DCRSR, DCRDR, DEMCR)
- FPB
- DWT
- ITM
- NVIC
- Crossbar bus switch
- Private peripheral bus

## 25.3 Boot

This section describes the boot sequence, including sources and options.

### 25.3.1 Boot sources

This MCU supports cold booting from internal flash memory.

When the MCU boots from internal flash memory, the reset vectors are located at address 0x0 (initial SP\_main) and 0x4 (initial PC).

The MCU also supports boot from RAM by relocating the exception vector table to RAM. This is implemented through a programmable Vector Table Offset Register (VTOR) in NVIC module.

The MCU supports serial code download via

- CAN
- LIN
- SPI etc.

The application developer can write their own flash memory based boot loaders or adapt the ones available at <http://www.nxp.com>. These boot loaders are then used to configure and use the communication protocol to perform mass serial download. For instance, the CAN module can be used to transfer data into its own message buffers, then the DMA module can be used to move the data into the main system RAM. Once the download is completed, the core can be used to transfer the new downloaded code into the flash memory area.

### 25.3.2 FOPT boot options

The **FOPT** register in the Flash Memory module allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's option byte in the flash memory configuration field. The default setting for all values in the FTFC\_FOPT register is logic 1 since it is copied from the option byte residing in flash memory, which has all bits as logic 1 in the flash memory erased state. To configure for alternate settings, program the appropriate bits in the NVM option byte. The new settings take effect on subsequent POR and any system reset. For more details on programming the option byte, see [the flash memory chapter](#).

The MCU uses **FOPT** to configure the MCU at reset as shown in this table.

**Table 25-2. FTFC\_FOPT definition**

| Bit number | Field               | Value                                                                                                                                                                                                                      | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

1. Not available in the S32K14xW devices

### 25.3.3 Boot sequence

At power up, the on-chip regulator holds the system in a POR state until the input supply is above the POR threshold. The system continues to be held in this static state until the internally regulated supplies have reached a safe operating voltage as determined by the LVD. The mode controller reset logic then controls this sequence to exit reset:

1. A system reset is held on internal logic, the RESET\_B pin is driven out low, and the SCG is enabled in its default clocking mode.
2. Required clocks are enabled (core clock, system clock, flash clock, and any bus clocks that do not have clock gate control reset to disabled).

3. The system reset on internal logic continues to be held, but the flash controller is released from reset and begins initialization operation while the reset control logic continues to drive the RESET\_B pin low.
4. Early in reset sequencing, the NVM option byte is read and stored to the flash memory module's FOPT register. If the LPBOOT is programmed for an alternate clock divider reset value, the system/core clock is switched to a slower clock speed.
5. When flash memory initialization completes, the RESET\_B pin is released. If RESET\_B continues to be asserted (an indication of a slow rise time on the RESET\_B pin or external drive in low), the system continues to be held in reset. Once the RESET\_B pin is detected high, the core clock is enabled and the system is released from reset.
6. When the system exits reset, the processor sets up the stack, program counter (PC), and link register (LR). The processor reads the start SP (SP\_main) from vector-table offset 0. The core reads the start PC from vector-table offset 4. LR is written to 0xFFFF\_FFFF.
7. If FlexNVM is enabled, the flash memory controller continues to restore the FlexNVM data. This data is not available immediately out of reset and the system should not access this data until the flash controller completes this initialization step as indicated by the [EEERDY](#) flag.

Subsequent system resets follow this same reset flow.

## Chapter 26

# Reset Control Module (RCM)

### 26.1 Chip-specific RCM information

High voltage detect (HVD) reset is not supported on this device. References to HVD reset or HVD trip must be ignored. The SACKERR timing is 0.5 s.

On this device, LVD (Low voltage detect) and LVR (Low voltage reset) events trigger LVD reset and hence Chip POR. Chip POR is triggered by POR, LVR or LVD events. The PMC\_LVDSC1[LVDRE] is used to gate LVD only, and has no effect on LVR generation. With PMC\_SC1[LVDRE] disabled, LVRs can still generate reset to system. See [Low Voltage Detect \(LVD\) System](#).

Wait mode is not supported on this device. See [Module operation in available power modes](#) for details on available power modes.

LPO128K\_CLK is used as low power clock for reset pin filter.

See [ARM Cortex-M4 Devices Generic User Guide](#) (for S32K14x and S32K14xW devices) and [ARM Cortex-M0 Devices Generic User Guide](#) (for S32K11x devices) for details on 'lockup' event.

#### 26.1.1 RCM register information

Following bit fields details CMU reset source and are available in S32K11x variants only:

- [RCM\\_PARAM\[ECMU\\_LOC\]](#),
- [RCM\\_SRS\[CMU\\_LOC\]](#),
- [RCM\\_SSRS\[SCMU\\_LOC\]](#), and
- [RCM\\_SRIE\[CMU\\_LOC\]](#).

Following bit fields details reset caused by a loss of lock in the SCG PLL/FLL and are available in S32K14x and S32K14xW variants only:

- [RCM\\_PARAM\[ELOL\]](#),

- [RCM\\_SRS\[LOL\]](#), and
- [RCM\\_SSRS\[SLOL\]](#).

### NOTE

The read of the RCM registers is affected during EEERAM commands. For more information see note 'During execution of the SetRAM 0xFF' in [Chip-specific FTFC information](#).

## 26.2 Reset pin filter operation in STOP1/2 modes

The reset pins filtering in STOP1/2 mode is as follows:

- STOP1: Both RUN mode and STOP mode filters can operate. The filter with lower pulse duration dominates.
- STOP2: RUN mode filter operates.

## 26.3 Introduction

Information found here describes the registers of the Reset Control Module (RCM). The RCM implements many of the reset functions for the chip. See the chip's reset chapter for more information.

See [AN4503: Power Management for Kinetis and ColdFire+ MCUs](#) for further details on using the RCM.

## 26.4 Reset memory map and register descriptions

The RCM Memory Map/Register Definition can be found [here](#).

The Reset Control Module (RCM) registers provide reset status information and reset filter control.

### NOTE

The RCM registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

## RCM memory map

| Address offset (hex) | Register name                                     | Width (in bits) | Access | Reset value                 | Section/ page              |

**26.4.3 System Reset Status Register (RCM\_SRS)**

This register includes read-only status flags to indicate the source of the most recent reset. Note that multiple flags can be set if multiple reset events occur at the same time. The reset state of these bits depends on what caused the MCU to reset.

**NOTE**

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x82
- LVD (without POR) — 0x02
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 0h base + 8h offset = 8h

## 26.4.5 Sticky System Reset Status Register (RCM\_SSRS)

This register includes status flags to indicate all reset sources since the last POR or LVD that have not been cleared by software. Software can clear the status flags by writing a logic one to a flag.

Address: 0h base + 18h offset = 18h

**26.4.6 System Reset Interrupt Enable Register (RCM\_SRIE)**

This register provides the option to delay the assertion of a system reset for a period of time (DELAY field) while an interrupt is generated. When an interrupt for a reset source is enabled, software has time to perform a graceful shutdown. A Chip POR source cannot be delayed by this feature. The SRS updates only after the system reset occurs.

**NOTE**

The reset delay feature requires the LPO clock to remain active.

**NOTE**

This register is reset on Chip POR only, it is unaffected by other reset types.

# Chapter 27

## Clock Distribution

### 27.1 Introduction

This chapter presents the clock architecture overview of this device, clock distribution, module clocks, and clock terminology. The System Clock Generator (SCG) module is used to generate most of the clocks used by the device. The SCG module controls which clock source (internal references, external crystals, external clocks) is used to derive system clocks. The SCG also divides the selected clock source into a variety of clock domains, including clocks for system bus masters, system bus slaves, and flash memory.

The clock generation circuitry provides several clock dividers and selectors allowing different modules to be clocked at a frequency specific for that module. Clock generation logic also implements module specific clock gating allowing modules to be individually disabled. Thus, allowing optimization for performance or low power.

Various modules have specific clocks that can be generated from FIRC\_CLK, SIRC\_CLK, SOSC\_CLK, SPLL\_CLK, or Power Management Controller (PMC) clock signal (LPO128K\_CLK). In addition, modules specific clocks that can be configured from alternate sources. Clock selection for most modules is controlled by the PCC module.

### 27.2 High level clocking diagram

The following diagram shows the high-level clocking architecture and various clock sources for this device.

## Clock definitions

1. The source of HCLK (to Arm® Cortex® modules) is CORE\_CLK. See section 'Clock definitions' for CORE\_CLK and BUS\_CLK
2. QSPI clocks are applicable for S32K148 only and Reserved for others. See QuadSPI clicking diagram in table 'Peripheral module clocking'
3. For S32K11x, inputs and muxes connected to PCC are Reserved. Also SPLLDIVx\_CLK are Reserved as indicated in **RED**
4. Available only in S32K11x as indicated in **BLUE**
5. Available only in S32K14xW as indicated in **YELLOW**

**Figure 27-1. Clocking diagram**

## 27.3 Clock definitions

The following table describes clocks shown in [Figure 27-1](#) and other sections of this document.

Table 27-1. Clock descriptions

| Clock name                                      | Related clock selector    | Related clock divider                                                   | Description                                                                                                                                                                        |
|-------------------------------------------------|---------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PREDIV_SYS_CLK <sup>1</sup>                     | SCG_xCCR[SCS]             | —                                                                       | Clocks the QSPI memory in HSRUN 80 mode.                                                                                                                                           |
| CORE_CLK <sup>2</sup>                           | SCG_xCCR[SCS]             | SCG_xCCR[DIVCORE]<br>(÷ 1...16)                                         | Clocks the Arm core, divided by DIVCORE bits inside SCG.                                                                                                                           |
| SYS_CLK <sup>2</sup>                            | SCG_xCCR[SCS]             | SCG_xCCR[DIVCORE]<br>(÷ 1...16)                                         | Clocks the Crossbar, NVIC, Flash controller, FTM, PDB, and so on.                                                                                                                  |
| BUS_CLK                                         | SCG_xCCR[SCS]             | SCG_xCCR[DIVBUS]<br>(÷ 1...16)                                          | Clocks the chip peripherals.                                                                                                                                                       |
| FLASH_CLK <sup>3</sup><br>(SCG_SLOW_CLK in SCG) | SCG_xCCR[SCS]             | SCG_xCCR[DIVSLOW]<br>(÷ 1...8)                                          | Clocks the flash module.                                                                                                                                                           |
| SPLL_CLK <sup>4</sup>                           | —                         | —                                                                       | Output of PLL (VCO_CLK ÷ 2)                                                                                                                                                        |
| SIRC_CLK                                        | —                         | —                                                                       | Output clock of Slow IRC.                                                                                                                                                          |
| FIRC_CLK                                        | —                         | —                                                                       | Output clock of Fast IRC.                                                                                                                                                          |
| SOSC_CLK                                        | SCG_SOSCCFG[EREFS]        | —                                                                       | System oscillator clock. Can be either the EXTAL pin or output of oscillator (SOSC).<br><br><b>NOTE:</b> ERCLK/OSCERCLK stands for the same clock source, in some module chapters. |
| RTC_CLKOUT                                      | —                         | —                                                                       | RTC oscillator output driving external pin.                                                                                                                                        |
| LPO32K_CLK                                      | SIM_LPOCLKS[CLK32SEL]     | A fixed divide by 4 of LPO_CLK drives 01b input of RTC_CLK multiplexer. | Source clock for RTC.                                                                                                                                                              |
| LPO128K_CLK                                     | —                         | —                                                                       | Always on low power oscillator clock generated by PMC.                                                                                                                             |
| SCG_CLKOUT                                      | SCG_CLKOUTCNFG[CLKOUTSEL] | —                                                                       | SCG output clock that can be driven by SOSC_CLK, SIRC_CLK, FIRC_CLK, SPLL_CLK <sup>4</sup> , or SCG_SLOW_CLK (FLASH_CLK).                                                          |
| LPO_CLK                                         | SIM_LPOCLKS[LPOCLKSEL]    | —                                                                       | Clock output generated from one of three LPO clocks sources (LPO128K_CLK, LPO32K_CLK, LPO1K_CLK).                                                                                  |
| CLKOUT                                          | SIM_CHIPCTL[CLKOUTSEL]    | SIM_CHIPCTL[CLKOUTDIV]<br>(÷ 1...8)                                     | Selected from one of eight internal clock sources.                                                                                                                                 |
| VCO_CLK <sup>4</sup>                            | —                         | —                                                                       | VCO output clock within PLL. Its frequency = SPLL_CLK × 2.                                                                                                                         |
| SPLLDIV1_CLK <sup>4</sup>                       | —                         | SCG_SPLLDIV[SPLLDIV1]<br>(÷ 1, 2, 4, 8, 16, 32, 64, or output disabled) | Divided SPLL_CLK<br><br>This should be configured to 80MHz or less in RUN mode and to 112 MHz or less in HSRUN mode.                                                               |
| SPLLDIV2_CLK <sup>4</sup>                       | —                         | SCG_SPLLDIV[SPLLDIV2]<br>(÷ 1, 2, 4, 8, 16, 32, 64, or output disabled) | Divided SPLL_CLK<br><br>This should be configured to 40 MHz or less in RUN mode and 56 MHz or less in HSRUN mode.                                                                  |

| SOSCDIV2_CLK | —                      | SCG_SOSCDIV[SOSCDIV2]<br>(÷ 1, 2, 4, 8, 16, 32, 64, or<br>output disabled)    | Divided SOSC_CLK<br>This should be configured to 40 MHz<br>or less in RUN/HSRUN mode.                                          |

1. Only available in S32K148
2. SYS\_CLK/CORE\_CLK must not be configured to less than BUS\_CLK.
3. For FLASH\_CLK operating range during parallel boot see [Device Boot modes](#)
4. Only available in S32K14x series

**NOTE**

Configuring DIVSLOW\_CLK to lower frequencies than supported flash frequencies mentioned in datasheet (fFLASH) adds wait states and no power saving. It is recommended to configure DIVSLOW\_CLK as close to fFLASH.

## 27.4 Internal clocking requirements

The clock dividers are programmed via the SCG module's clock divider registers. The following requirements must be met when configuring the clocks for this chip:

- CORE\_CLK and SYS\_CLK clock frequency must be 112 MHz or less in HSRUN mode and 80 MHz in normal RUN mode (but not configured to be less than BUS\_CLK).
- BUS\_CLK frequency must be programmed to 56 MHz or less in HSRUN, 48 MHz or less in RUN (when using PLL as system clock source maximum bus clock

frequency is 40 MHz. See Option 1 and 3 below ), and an integer divide of the CORE\_CLK.

- FLASH\_CLK frequency must be programmed to 28 MHz or less in HSRUN, 26.67 MHz or less in RUN, and an integer divide of the CORE\_CLK. The core clock to flash clock ratio is limited to a max value of 8.

The following are a few of the common clock configurations for this chip in the four clocking modes:

Option 1: Slow RUN (typically using the undivided FIRC)<sup>1</sup>, using the following [Memory Map/Register Definition](#) register settings:

- SCG\_RCCR[SCS] = 0011b
- SCG\_RCCR[DIVCORE] = 0000b
- SCG\_RCCR[DIVBUS] = 0000b
- SCG\_RCCR[DIVSLOW] = 0001b

**Table 27-2. Slow RUN example**

| Clock     | Frequency                      |                                |
|-----------|--------------------------------|--------------------------------|
|           | S32K14x and S32K11x            | S32K14xW                       |
| CORE_CLK  | 48 MHz                         | 48 MHz                         |
| SYS_CLK   | 48 MHz                         | 48 MHz                         |
| BUS_CLK   | 48 MHz (max freq. in RUN mode) | 48 MHz (max freq. in RUN mode) |
| FLASH_CLK | 24 MHz                         | 16 MHz                         |

Option 2: Normal RUN (with VCO\_CLK = 320 MHz, SPLL\_CLK = 160 MHz), using the following [Memory Map/Register Definition](#) register settings:

- SCG\_RCCR[SCS] = 0110b
- SCG\_RCCR[DIVCORE] = 0001b
- SCG\_RCCR[DIVBUS] = 0001b
- SCG\_RCCR[DIVSLOW] = 0010b

**Table 27-3. Normal RUN example**

| Clock     | Frequency                         |                                |
|-----------|-----------------------------------|--------------------------------|
|           | S32K14x and S32K11x               | S32K14xW                       |
| CORE_CLK  | 80 MHz                            | 80 MHz                         |
| SYS_CLK   | 80 MHz                            | 80 MHz                         |
| BUS_CLK   | 40 MHz                            | 40 MHz                         |
| FLASH_CLK | 26.67 MHz (max freq. in RUN mode) | 20 MHz (max freq. in RUN mode) |

1. Default configuration after reset. FIRC\_CLK = 48 MHz.

Option 3: Normal RUN (with VCO\_CLK = 256 MHz, SPLL\_CLK = 128 MHz), using the following [Memory Map/Register Definition](#) register settings:

- SCG\_RCCR[SCS] = 0110b
- SCG\_RCCR[DIVCORE] = 0001b
- SCG\_RCCR[DIVBUS] = 0001b
- SCG\_RCCR[DIVSLOW] = 0010b

**Table 27-4. Normal RUN example**

| Clock     | Frequency           |          |
|-----------|---------------------|----------|
|           | S32K14x and S32K11x | S32K14xW |
| CORE_CLK  | 64 MHz              | 64 MHz   |
| SYS_CLK   | 64 MHz              | 64 MHz   |
| BUS_CLK   | 32 MHz              | 32 MHz   |
| FLASH_CLK | 21.33 MHz           | 16 MHz   |

Option 4: High Speed RUN (with VCO\_CLK = 224 MHz, SPLL\_CLK = 112 MHz), using the following [Memory Map/Register Definition](#) register settings:

- SCG\_HCCR[SCS] = 0110b
- SCG\_HCCR[DIVCORE] = 0000b
- SCG\_HCCR[DIVBUS] = 0001b
- SCG\_HCCR[DIVSLOW] = 0011b

**Table 27-5. High Speed RUN example**

| Clock     | Frequency |
|-----------|-----------|
|           | S32K14x   |
| CORE_CLK  | 112 MHz   |
| SYS_CLK   | 112 MHz   |
| BUS_CLK   | 56 MHz    |
| FLASH_CLK | 28 MHz    |

### NOTE

All frequencies listed in table above are maximum for HSRUN mode.

Option 5: High Speed RUN 80 (with VCO\_CLK = 320 MHz, SPLL\_CLK = 160 MHz), using the following [Memory Map/Register Definition](#) register settings:

- SCG\_HCCR[SCS] = 0110b
- SCG\_HCCR[DIVCORE] = 0001b
- SCG\_HCCR[DIVBUS] = 0001b
- SCG\_HCCR[DIVSLOW] = 0010b

**Table 27-6. High Speed RUN 80 example (mode used by QuadSPI only)**

| Clock     | Frequency                                          |
|-----------|----------------------------------------------------|
|           | S32K14x                                            |
| CORE_CLK  | 80 MHz                                             |
| SYS_CLK   | 80 MHz                                             |
| BUS_CLK   | 40 MHz                                             |
| FLASH_CLK | 26.67 MHz<br>(maximum<br>frequency in RUN<br>mode) |

Option 6: Very Low Power RUN, VLPR (with SIRC\_CLK = 8 MHz), using the following [Memory Map/Register Definition](#) register settings:

- SCG\_VCCR[SCS] = 0010b (SIRC\_CLK)
- SCG\_VCCR[DIVCORE] = 0001b
- SCG\_VCCR[DIVBUS] = 0000b
- SCG\_VCCR[DIVSLOW] = 0011b

**Table 27-7. Very low power RUN example**

| Clock     | Frequency           |          |
|-----------|---------------------|----------|
|           | S32K14x and S32K11x | S32K14xW |
| CORE_CLK  | 4 MHz               | 1 MHz    |
| SYS_CLK   | 4 MHz               | 1 MHz    |
| BUS_CLK   | 4 MHz               | 1 MHz    |
| FLASH_CLK | 1 MHz               | 0.25 MHz |

Following table summarizes the maximum frequencies and example configurations for each internal clock

## Internal clocking requirements

| Clock                | HSRUN   |          |         | RUN                                                   |          |         | VLPR                |          | Notes                                                                                                       |
|----------------------|---------|----------|---------|-------------------------------------------------------|----------|---------|---------------------|----------|-------------------------------------------------------------------------------------------------------------|
|                      | S32K14x | S32K14xW | S32K11x | S32K14x                                               | S32K14xW | S32K11x | S32K14x and S32K11x | S32K14xW |                                                                                                             |
| CORE_CLK,<br>SYS_CLK | 112 MHz | NA       | NA      | 80 MHz                                                | 80 MHz   | 48 MHz  | 4 MHz               | 1 MHz    | Must be configured to be more than or equal to BUS_CLK.                                                     |
| BUS_CLK              | 56 MHz  | NA       | NA      | 48 MHz (40 MHz when using PLL as system clock source) | 48 MHz   | 48 MHz  | 4 MHz               | 1 MHz    | Must be integer divide of the CORE_CLK.                                                                     |
| FLASH_CLK            | 28 MHz  | NA       | NA      | 26.67 MHz                                             | 20 MHz   | 24 MHz  | 1 MHz               | 0.25 MHz | Must be integer divide of the CORE_CLK. The core clock to flash clock ratio is limited to a max value of 8. |

**NOTE**

All frequencies listed in table above are maximum for VLPR mode.

**NOTE**

All asynchronous clock sources will also be restricted to 4 MHz in VLPR/VLPS mode as configured in SCG\_SIRCDIV.

### 27.4.1 Clock divider values after reset

The default configuration out of reset has the CPU clocked by the Fast IRC (FIRC\_CLK). The clocks (for example, CORE\_CLK, FLASH\_CLK, and BUS\_CLK) are configured in the SCG module (see [Memory Map/Register Definition](#)).

### 27.4.2 HSRUN mode clocking

Clock dividers should not be modified while the chip is operating in HSRUN mode. They must be configured prior to entering HSRUN mode to guarantee:

- CORE\_CLK/SYS\_CLK is less than or equal to 112MHz
- BUS\_CLK is less than or equal to 56 MHz
- FLASH\_CLK is less than or equal to 28 MHz

### 27.4.3 VLPR mode clocking

Clock dividers should not be modified while the chip is operating in VLPR mode. They must be configured prior to entering VLPR mode to guarantee:

- CORE\_CLK/SYS\_CLK and BUS\_CLK are less than or equal to 4 MHz and 1 MHz for S32K14x/S32K11x and S32K14xW variants respectively.
- FLASH\_CLK is less than or equal to 1 MHz and 0.25 MHz for S32K14x/S32K11x and S32K14xW variants respectively.

**NOTE**

- For S32K14x and S32K11x variants: All asynchronous clock sources will also be restricted to 4 MHz in VLPR/VLPS mode as configured in SCG\_SIRCDIV.
- For S32K14xW variants: All asynchronous clock sources will also be restricted to 1 MHz in VLPR/VLPS mode as configured in SCG\_SIRCDIV.

## 27.4.4 VLPR/VLPS mode entry

When entering VLPR/VLPS mode, the system clock should be SIRC. The FIRC, SOSC, and SPLL must be disabled by software in RUN mode before making any mode transition. Ensure that CMU is gated by its PCC.CGC before entering STOP/VLPS/CPO mode.

## 27.5 Clock Gating

The clock to each module can be individually gated on and off using the PCC module. After any reset, PCC disables the clock to the corresponding module to conserve power. Prior to initializing a module, set the corresponding clock gating control bits in PCC register to enable the clock. Before turning off the clock, make sure to disable the module.

Any bus access to a peripheral that has its clock disabled generates an error termination.

## 27.6 Module clocks

The following table summarizes the clocks that can be used by each of the modules.

**Table 27-8. Peripheral clock summary**

| Module name    | Bus interface clock <sup>1</sup> | Bus interface clock <sup>1</sup> gating | Peripheral functional clock                                     | Additonal clocks | Comments and maximum frequencies      |
|----------------|----------------------------------|-----------------------------------------|-----------------------------------------------------------------|------------------|---------------------------------------|
|                |                                  | Gated by [CGC] of PCC                   | Clocks controlled by [PCS] of PCC                               |                  |                                       |
| Communications |                                  |                                         |                                                                 |                  |                                       |
| LPUART         | BUS_CLK                          | Yes                                     | SPLLDIV2_CLK,<br>FIRCDIV2_CLK,<br>SIRCDIV2_CLK,<br>SOSCDIV2_CLK | —                | Maximum frequency governed by BUS_CLK |
| LPSPi          | BUS_CLK                          | Yes                                     | SPLLDIV2_CLK,<br>FIRCDIV2_CLK,<br>SIRCDIV2_CLK,<br>SOSCDIV2_CLK | —                | Maximum frequency governed by BUS_CLK |
| LPI2C          | BUS_CLK                          | Yes                                     | SPLLDIV2_CLK,<br>FIRCDIV2_CLK,<br>SIRCDIV2_CLK,<br>SOSCDIV2_CLK | —                | Maximum frequency governed by BUS_CLK |

*Table continues on the next page...*

Table 27-8. Peripheral clock summary (continued)

| Module name         | Bus interface clock <sup>1</sup> | Bus interface clock <sup>1</sup> gating | Peripheral functional clock                                                                  | Additional clocks                                    | Comments and maximum frequencies                                                                                                                                                              |
|---------------------|----------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Table 27-8. Peripheral clock summary**

| Module name | Bus interface clock <sup>1</sup> | Bus interface clock <sup>1</sup> gating | Peripheral functional clock       | Additional clocks | Comments and maximum frequencies |
|-------------|----------------------------------|-----------------------------------------|-----------------------------------|-------------------|----------------------------------|
|             |                                  | Gated by [CGC] of PCC                   | Clocks controlled by [PCS] of PCC |                   |                                  |
|             |                                  |                                         | SOSCDIV1_CLK                      |                   |                                  |

1. Refers to module's interface clock and should not be misinterpreted as BUS\_CLK
2. RTC\_CLK is the output from the multiplexer that uses SIM\_LPOCLKS[RTCCLKSEL] for source selection (See [Figure 1](#) for details).
3. FlexIO peripheral clock should not be more than twice of FlexIO bus interface clock. For fast access to FlexIO register (FLEXIO\_CTRL[FASTACC]=1), FlexIO peripheral clock can be twice of FlexIO Bus interface clock.
4. In S32K11x variants, 'SYS\_CLK > 1.5x the protocol clock' requirement is not applicable but the software needs to maintain following relationship:
  - CAN bit time > (3 x CANCLK period) + (3 x SYS\_CLK period)
5. Only applicable for S32K14xW variants
6. LPO\_CLK is the output from the multiplexer that uses SIM\_LPOCLKS[LPOCLKSEL] for source selection (See [Figure 1](#) for details).
7. Do not change the clock control settings to the flash memory whilst simultaneously accessing the flash memory. Instead, it is recommended to execute from SRAM when a change in frequency is needed.
8. The maximum conversion clock frequency is 50 MHz. At any time, the conversion clock frequency should be less than the ADC bus interface clock frequency. See the device datasheet for ADC specifications.
9. Refer to [External signal description](#) for clocking restrictions.

**NOTE**

The above clock selections are controlled in the [PCC](#) module (column 4 of [Table 27-8](#)).

**NOTE**

- SIRC and LPO\_CLK are the valid clock sources for VLP\* modes.
- SPLL and FIRC are the valid clock sources for HSRUN mode.

The following table summarizes the clocks that can be used by each of the modules.

Table 27-9. Peripheral module clocking (continued)

| Modules | PCC multiplexer                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPTMR   | <p>The prescaler and glitch filter of the LPTMR0 module can be clocked from misc sources determined by the PCC_LPTMR[PCS] control bitfield and LPTMR0_PSR[PCS] bitfield. The LPTMR_PSR[PCS] bitfield is used for internal LPTMR to select the clock source. The supported clock sources on this device are shown in following figure.</p> <p><b>NOTE:</b> The clock selected must remain enabled if the LPTMR is to continue operating in all required low power modes.</p> |
| TPIU    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SAI     | <p>The BCLK can either be externally provided through BCLK pin or can be internally generated in internal bit clock mode using SAI internal divider by configuring SAI<sub>n</sub>_RCR2[MSEL]/SAI<sub>n</sub>_TCR2[MSEL] and SAI<sub>n</sub>_RCR2[DIV]/SAI<sub>n</sub>_TCR2[DIV].</p>                                                                                                                                                                                       |

**Table 27-9. Peripheral module clocking (continued)**

| Modules | PCC multiplexer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         |  <p><b>NOTE:</b> SIM_MISCTRL0 bit 24 and 25 are used to control which clock (external or internally generated) is used by MAC in RMII mode only.</p> <p><b>NOTE:</b> The following sequence should be following for internally generated RMII clock enabling:</p> <ol style="list-style-type: none"> <li>1. PHY stops driving the Tx_clk</li> <li>2. SCG_SOSCDIV[SOSCDIV1] is configured to disable SOSCDIV1_CLK</li> <li>3. SIM_MISCTRL0[RMII_CLK_OBE] is configured to 1 configure pad output buffer</li> <li>4. Pad PTD11 is configured for MII_RMII_TX_CLK function by configuring PCR_PTD11[SSS]</li> <li>5. SIM_MISCTRL0[RMII_CLK_SEL] is configured to enable SOSCDIV1_CLK as internal clock</li> <li>6. SCG_SOSCDIV[SOSCDIV1] is configured to enable SOSCDIV1_CLK</li> </ol> |
| CMU     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

1. For S32K14x and S32K11x variants
2. For S32K14xW variants

**NOTE**

While changing peripheral clock source/divider configuration, the corresponding module should be disabled.

# Chapter 28

## System Clock Generator (SCG)

### 28.1 Chip-specific SCG information

Wait mode is not supported on this device. See [Module operation in available power modes](#) for details on available power modes.

#### NOTE

- SPLL mode is not available in S32K11x series of devices.
- HSRUN mode is not available in S32K14xW and S32K11x series of devices.
- SCG\_SIRCCSR[SIRCLPEN] bit field is applicable for VLPS mode only.
- SCG\_SIRCCSR[SIRCSTEN] bit field is not applicable and should be ignored.
- For S32K11x and S32K14xW series of devices only, writing to SCG\_HCCR will give transfer error.
- For S32K14xW series of devices only, SPLLCFG[SOURCE] is configurable to support FIRC as reference for SPLL.

#### 28.1.1 Register reset values

The reset values of some SCG registers vary across the products in the series. The following table shows these reset values for each product.

Table 28-1. SCG register reset values

| Register          | S32K116 | S32K118 | S32K142 | S32K144 | S32K144W | S32K146 | S32K148 |
|-------------------|---------|---------|---------|---------|----------|---------|---------|
| SCG_RCCR[DIVSLOW] | 0001    | 0001    | 0001    | 0001    | 0010     | 0001    | 0001    |

## 28.1.2 Supported frequency ranges

This section describes the supported frequency ranges.

### 1. SCG\_SOSCCFG[RANGE]

- 00 Reserved
- 01 Reserved
- 10 Medium frequency range selected for the crystal oscillator of 4 MHz to 8 MHz.
- 11 High frequency range selected for the crystal oscillator of 8 MHz to 40 MHz.

### 2. SCG\_SIRCCFG[RANGE]

- 0 Reserved
- 1 Slow IRC high range clock (8 MHz )

## 28.1.3 Oscillator and SPLN guidelines

If the current system clock is SOSC, then following should be taken care by software before disabling SOSC:

- Configure all reset sources as 'Interrupt' (not as 'Reset') via RCM\_SRIE
- The SOSC should be disabled via SCG\_SOSCCSR[SOSCEN]
- After disabling SOSC, configure the reset source back to reset via RCM\_SRIE
- When SPLN is enabled, both LOC and LOL must be configured as reset only (SOSCCSR[SOSCCMRE] and SPLNCSR[SPLNLCMRE] must be 1 and RCM\_SRIE[LOC], RCM\_SRIE[LOL] must be 0). The only exception is during standard clock switching, in which case the 'clock switching sequence' protocol must be followed.

### NOTE

If PLL is used, then oscillator needs to be in high range only, SCG\_SOSCCFG[RANGE] on 11 as used in reference clock.

See note in section [IO Signal Table](#)

## 28.1.4 System clock switching

For any clock switching of system clock, follow the below steps:

- Before doing a clock switch, configure all reset sources to be 'Reset' (not as Interrupt) via RCM\_SRIE.
- Program each reset source as Interrupt via RCM\_SRIE for a minimum delay time of 10 LPO.
- Execute the clock switch

- Wait/Poll for the clock switch to complete
- Configure every reset source back to original intended reset configuration (Interrupt or Reset) via RCM\_SRIE

### NOTE

LOC flag would be raised when SOSC pulses are not detected for 8 to 16 clock cycles of SIRC/256. Hence, the LOC indication through reset to the system from the time when oscillator is cut off will vary from 256  $\mu$ s to 512  $\mu$ s.

## 28.1.5 System clock and clock monitor requirement

1. **System clock source SOSC/SPLL requirement:** Ensure below sequence is followed while switching system clock to SOSC/SPLL:
  - a. System clock source (SOSC/SPLL) is enabled
  - b. Clock monitors (SOSCCSR[SOSCCME] and SPLLCR[SPLLCME]) and their corresponding reset event monitors (SOSCCSR[SOSCCMRE] and SPLLCR[SPLLCMRE]) are enabled for SOSC/SPLL
  - c. SOSC/SPLL is selected as system clock source
2. **SOSC/SPLL clock monitor disable sequence requirement:** Ensure below sequence for disabling clock monitors while switching system clock source from SOSC/SPLL:
  - a. System clock source switched from SOSC/SPLL
  - b. Disable Clock monitors (SOSCCSR[SOSCCME] and SPLLCR[SPLLCME]) and their corresponding reset event monitors (SOSCCSR[SOSCCMRE] and SPLLCR[SPLLCMRE]) for SOSC/SPLL

It is imperative to follow the above guidelines to safeguard the device operation against loss of clock scenarios if system clock source malfunction due to any reason.

## 28.2 Introduction

The system clock generator (SCG) module provides the system clocks of the MCU. The SCG contains a system phase-locked loop (SPLL), a slow internal reference clock (SIRC), a fast internal reference clock (FIRC), and the system oscillator clock (SOSC). The SPLL is sourced by either the SOSC reference clock or the FIRC reference clock. The SCG can select either the output clock of the SPLL or a SCG reference clock (SIRC, FIRC, and SOSC) as the source for the MCU system clocks. The SCG also supports operation with crystal oscillators, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock (which are also available as clock sources for the MCU systems clocks).

## 28.2.1 Features

Key features of the SCG module are:

- System Phase-locked loop (SPLL):
  - Voltage-controlled oscillator (VCO)
  - Selectable Internal or External reference clock is used as the PLL source
  - Modulo VCO frequency divider
  - Phase/Frequency detector
  - Integrated loop filter
  - Can be selected as the clock source for the MCU system clocks
  - 2 programmable post-dividers clock outputs, which can be used as clock sources for other on-chip peripherals
- 2 Internal reference clock (IRC) generators:
  - Fast IRC clock with programmable High and Low frequency range
  - Fast clock can be used as a source for System PLL
  - Either the slow or the fast clock can be selected as the clock source for the MCU system clocks
  - 2 programmable post-divider clock outputs for each IRC, which can be used as clock sources for other on-chip peripherals
- System Crystal Oscillator:
  - Can be used as a source for the System PLL
  - Can be selected as the clock source for the MCU system clocks
- Clock monitor with reset and interrupt request capability for SPLL, SOSC, clocks
- Lock detector with interrupt request capability for use with the SPLL
- Each of the clock sources have reference dividers for clocking on-chip modules and peripherals, namely:
  - SPLLDIV1\_CLK / SPLLDIV2\_CLK
  - FIRCDIV1\_CLK / SCG\_FIRCDIV2\_CLK

- SIRCDIV1\_CLK / SIRCDIV2\_CLK
- SOSCDIV1\_CLK / SOSCDIV2\_CLK

See the Clock Distribution Chapter for more information.

## 28.3 Memory Map/Register Definition

This section includes the memory map and register definition.

The SCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus transfer error. Read accesses may be performed in both supervisor and user mode.

### NOTE

For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.

**SCG memory map**

| Address offset (hex) | Register name                                          | Width (in bits) | Access | Reset value                 | Section/ page               |

**28.3.3 Clock Status Register (SCG\_CSR)**

This register returns the currently configured system clock source and the system clock dividers for the core (DIVCORE) and peripheral interface clock (DIVSLOW). The SCG\_CSR reflects the configuration set by one of three clock control registers SCG\_RCCR, SCG\_VCCR, SCG\_HCCR.

**Note:** Writing to this register will result in a transfer error.

Address: 0h base + 10h offset = 10h

## 28.3.4 Run Clock Control Register (SCG\_RCCR)

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until new clock source is valid.

Address: 0h base + 14h offset = 14h

**28.3.5 VLPR Clock Control Register (SCG\_VCCR)**

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in VLPR mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in VLPR requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in VLPR, new system clock divide ratios will not take affect until new clock source is valid.

**28.3.6 HSRUN Clock Control Register (SCG\_HCCR)**

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in HSRUN mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in HSRUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in HSRUN, new system clock divide ratios will not take affect until new clock source is valid.

## 28.3.9 System OSC Divide Register (SCG\_SOSCDIV)

The SCG\_SOSCDIV register provides the control of clock trees which can be used to provide optional peripheral functional clocks, or alternative module clocks. Each clock tree has optional dividers of the input SOSC clock. Changes to SOSCDIV should be done when System OSC is disabled to prevent glitches to output divided clock.

### 28.3.10 System Oscillator Configuration Register (SCG\_SOSCCFG)

The SOSCCFG register cannot be changed when the System OSC is enabled. When the System OSC is enabled, writes to this register are ignored, and there is no transfer error.

Address: 0h base + 108h offset = 108h

### 28.3.15 Fast IRC Divide Register (SCG\_FIRCDIV)

Changes to FIRCDIV should be done when FAST IRC is disabled to prevent glitches to output divided clock.

Address: 0h base + 304h offset = 304h

|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24<br>SPLLVD      | <p>System PLL Valid</p> <p>Indicates when the SPLL clock is valid. When the System PLL (SPLL) is disabled, the System PLL Valid bit (SPLLVD) will clear without causing the System PLL Clock Error bit (SPLLERR) to get set. In a similar way, if the System PLL (SPLL) is using the System Oscillator (SOSC) as its reference clock, and a System OSC Clock Error (SOSCCSR[SOSCERR]) is detected, then the System PLL Valid bit (SPLLVD) will clear without asserting a System PLL Clock Error (SPLLERR).</p> <p>Lock detect is determined by a lock detect circuit. Three samples of lock detect determines whether or not the clock is valid.</p> <p><b>NOTE:</b> The System PLL Valid bit (SPLLVD) should only be used to verify that the SPLL is locked after initialization. To monitor the SPLL clock, ensure that the System PLL Clock Monitor is enabled, using the System PLL Clock Monitor bit (SPLLCM).</p> <p>0 System PLL is not enabled or clock is not valid<br/>1 System PLL is enabled and output clock is valid</p> |

### 28.3.18 System PLL Divide Register (SCG\_SPLLDIV)

Changes to SPLLDIV should be done when System PLL is disabled to prevent glitches to output divided clock.

Address: 0h base + 604h offset = 604h

### 28.3.19 System PLL Configuration Register (SCG\_SPLLCFG)

The SPLLCFG register cannot be changed when the System PLL is enabled. When the System PLL is enabled, writes to this register are ignored, and there is no transfer error.

The below information applies to VCO\_CLK.

The  $SPLL\_CLK = (VCO\_CLK)/2$

The  $VCO\_CLK = SPLL\_SOURCE / (PREDIV + 1) \times (MULT + 16)$

$SPLL\_SOURCE$  is the clock source selected from the  $SOURCE$  bitfield of this register.

Address: 0h base + 608h offset = 608h

## 28.4 Functional description

### 28.4.1 SCG Clock Mode Transitions

The following figure shows the valid clock mode transitions supported by SCG.

Slow IRC (SIRC) boot mode is not supported on this device.

## SCG Valid Mode Transitions

Figure 28-1. SCG Valid Mode Transition Diagram

**NOTE**

When a transition between run modes (RUN, HSRUN, VLRUN) is required, the SCG should complete the switch to the clock mode as defined in the SCG clock control register first. Once the switch to the clock mode is completed, the system can then initiate the request for the selected run mode.

For example, if a transition from RUN mode to VLRUN is required, first complete any required clock change. Initiate the VLRUN request **after** the clock change has completed.

The power modes are chip specific. For more details about power mode assignments, see power management and system mode control information.

The modes of operation listed in the following table are the valid modes for this implementation of the SCG.

**Table 28-4. SCG modes of operation**

| Mode                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Oscillator Clock (SOSC)       | <p>System Oscillator Clock (SOSC) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• RUN MODE: 0001 is written to RCCR[SCS].</li> <li>• SOSSEN = 1</li> <li>• SOSCVLD = 1</li> </ul> <p>In SOSC mode, SCGCLKOUT and system clocks are derived from the external System Oscillator Clock (SOSC).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Slow Internal Reference Clock (SIRC) | <p>Slow Internal Reference Clock (SIRC) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• RUN MODE: 0010 is written to RCCR[SCS].</li> <li>• VLRUN MODE: 0010 is written to VCCR[SCS] and 1 is written to SIRCCSR[SIRCLPEN].</li> <li>• SIRCEN = 1</li> <li>• SIRCVLD = 1</li> </ul> <p>In SIRC mode, SCGCLKOUT and system clocks are derived from the slow internal reference clock. Two frequency ranges are available for SIRC clock as described in the SIRCCFG[RANGE] register definition. Changes to SIRC range settings will be ignored when SIRC clock is enabled.</p> <p>Information regarding SIRC operation during normal and low power stop modes is found in the <a href="#">"Stop" row of this table</a>.</p> <p>See chip-specific information for supported frequency ranges.</p> |
| Fast Internal Reference Clock (FIRC) | <p>Fast Internal Reference Clock (FIRC) mode is the default clock mode of operation and is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• RUN MODE: 0011 is written to RCCR[SCS].</li> <li>• HSRUN MODE: 0011 is written to HCCR[SCS].</li> <li>• FIRCEN = 1</li> <li>• FIRCREGOFF = 0</li> <li>• FIRCVLD = 1</li> </ul> <p>In FIRC mode, SCGCLKOUT and system clocks are derived from the fast internal reference clock. Four frequency range settings are available for FIRC clock as described in the FIRC[RANGE] register definition. Changes to FIRC range settings will be ignored when FIRC clock is enabled.</p> <p>See chip-specific information for supported frequency ranges.</p>                                                                                                         |
| Sys PLL (SPLL)                       | <p>Sys PLL (SPLL) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• RUN MODE: 0110 is written to RCCR[SCS].</li> <li>• HSRUN MODE: 0110 is written to HCCR[SCS].</li> <li>• SPLLEN = 1</li> <li>• SPLLVD = 1</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

*Table continues on the next page...*

**Table 28-4. SCG modes of operation (continued)**

| Mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | In SPLL mode, the SCGCLKOUT and system clocks are derived from the output of PLL which is controlled by either the System Oscillator (SOSC) clock or the Fast internal reference clock (FIRC). The selected PLL clock frequency locks to a multiplication factor, as specified by its corresponding SCG_SPLLCFG[MULT], times the selected PLL reference frequency. The PLL's programmable reference divider must be configured to produce a valid PLL reference clock. This divide value is defined by the SCG_SPLLCFG[PREDIV] bits.                                                                                                |
| Stop | <p>Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the chapter that describes how modules are configured and SCG behaviour during Stop recovery. Entering Stop mode, all SCG clock signals are static except the following clocks which can continue to run and stay enabled in the following cases:</p> <p>SIRCCLK is available in Normal Stop and VLPS mode when all the following conditions become true:</p> <ul style="list-style-type: none"> <li>• SIRCCSR[SIRCEN] = 1</li> <li>• SIRCCSR[SIRCSTEN] = 1</li> <li>• SIRCCSR[SIRCLPEN] = 1 in VLPS</li> </ul> |

## Chapter 29

# Peripheral Clock Controller (PCC)

### 29.1 Chip-specific PCC information

For module specific clocking, see [Module clocks](#).

#### NOTE

While change a peripheral clock configurations (clock source, divider configurations, etc.), the corresponding module should be disabled:

- Clock should be CGC gated
- Module should be disabled by MDIS bit, if available

#### NOTE

- Before clock configuration changes, the user should ensure that module is disabled and not actively communicating / interacting and is in a quiescent state.
- For S32K144W, PCC\_LPIT additionally supports LPO\_CLK (configured with PCC\_LPIT[PCS]=111).

After clock switching, the module should be soft reset using soft reset bit (module software reset bit), if available.

SIM\_SDID[FEATURES] bit field overrides the PCC.PR status for the chip.

#### 29.1.1 PCC register information

The [PCC memory map](#) shows a superset of registers implemented for the S32K1xx series. Registers for instances unavailable in a particular variant are reserved.

S32K11x has two additional registers (PCC\_CMU0 and PCC\_CMU1) for CMU0 and CMU1 instances as described in the following sections. Similarly S32K144W has one register, PCC\_FTFM in place of PCC\_FTFC as described in the following sections.

## 29.1.1.1 PCC CMU0 Register (PCC\_CMU0)

### 29.1.1.1.1 Offset

| Register | Offset |
|----------|--------|
| PCC_CMU0 | F8h    |

### 29.1.1.1.2 Function

PCC Register

### 29.1.1.1.3 Diagram

|       |    |     |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|----|-----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bits  | 31 | 30  | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 29.2 Introduction

The Peripheral Clock Control (PCC) module provides clock control and configuration for on-chip peripherals. Each peripheral has its own clock control and configuration register.

## 29.3 Features

The PCC module enables software to configure the following clocking options for each peripheral:

- Interface clock gating
- Functional clock source selection
- Functional clock divide values

Below is a block diagram of the PCC module:

Figure 29-1. PCC Block Diagram

## 29.4 Functional description

The PCC module provides on-chip peripherals (modules) their own dedicated PCC registers for clock gating and configuration options. Each module's PCC register contains a clock gating control bit (CGC) for the module's interface clock. Before a module can be used, its interface clock must be enabled (CGC = 1) in the module's PCC register.

If a module has a functional clock, its PCC register may provide options for the clock source, selected by programming the Peripheral Clock Select (PCS) field. Optionally, a module may also have a clock divider, selected by programming the Peripheral Clock Divider (PCD) field along with a Fraction (FRAC) field. Before configuring a functional clock, the module's interface clock must be disabled (CGC = 0).

## 29.5 Memory map and register definition

Each module has its own dedicated PCC register, which controls the clock gating, clock source and divider (when applicable) for that specific module. See each module's PCC register for details.

PCC registers can be written only in supervisor mode using 32-bit accesses.

### NOTE

To configure the clocking options available to a given module or to modify an existing configuration, first disable the module's interface clock by writing 0 to its CGC bit.

## 29.6 PCC register descriptions

### 29.6.1 PCC memory map

PCC base address: 4006\_5000h

| Offset | Register                                     | Width<br>(In bits) | Access | Reset value |

## 29.6.5 PCC FlexCAN1 Register (PCC\_FlexCAN1)

### 29.6.5.1 Offset

| Register     | Offset |
|--------------|--------|
| PCC_FlexCAN1 | 94h    |

### 29.6.5.2 Function

This register is for the FlexCAN1 module.
